Paper 3

Wednesday 20 June 2018

Morning

Time allowed: 2 hours

Materials

For this paper you must have:

- the Periodic Table/Data Booklet, provided as an insert (enclosed)
- a ruler with millimetre measurements
- a scientific calculator, which you are expected to use where appropriate.

Instructions

- Use black ink or black ball-point pen.
- Fill in the boxes at the top of the page.
- Answer **all** questions.
- You must answer the questions in the spaces provided. Do **not** write outside the box around each page or on blank pages.
- All working must be shown.
- Do all rough work in this book. Cross through any work you do not want to be marked.

Information

- The marks for questions are shown in brackets.
- The maximum mark for this paper is 90.

Advice

- You are advised to spend about 70 minutes on **Section A** and 50 minutes on **Section B**.

Section A

Answer **all** questions in this section.

0 1

Iodide ions are oxidised to iodine by hydrogen peroxide in acidic conditions.

The rate equation for this reaction can be written as

$$\text{rate} = k[\text{H}_2\text{O}_2]^a[\text{I}^-]^b[\text{H}^+]^c$$

In an experiment to determine the order with respect to $\text{H}^+(\text{aq})$, a reaction mixture is made containing $\text{H}^+(\text{aq})$ with a concentration of $0.500 \text{ mol dm}^{-3}$

A large excess of both H_2O_2 and I^- is used in this reaction mixture so that the rate equation can be simplified to

$$\text{rate} = k_1[\text{H}^+]^c$$

0 1 . 1

Explain why the use of a large excess of H_2O_2 and I^- means that the rate of reaction at a fixed temperature depends only on the concentration of $\text{H}^+(\text{aq})$.

[2 marks]

H_2O_2 and I^- are in such large excess that the change in their concentrations is negligible, so their concentrations stay (effectively) constant.

So they have a constant effect on the rate (they are absorbed into k_1), and only the concentration of H^+ changes.

0 1 . 2

Samples of the reaction mixture are removed at timed intervals and titrated with alkali to determine the concentration of $\text{H}^+(\text{aq})$.

State and explain what must be done to each sample before it is titrated with alkali.

[2 marks]

Stop (quench) the reaction in each sample before titrating it, e.g. by diluting it with a large volume of cold water / cooling it in ice.

So that the $[\text{H}^+]$ does not keep changing (H^+ is not used up) while it is being titrated.

0 1 . 3 A graph of the results is shown in **Figure 1**.

Explain how the graph shows that the order with respect to $\text{H}^+(\text{aq})$ is zero.

[2 marks]

The graph is a straight line with a constant gradient, so the rate stays constant.

As $[\text{H}^+]$ decreases the rate does not change, so $[\text{H}^+]$ has no effect on the rate (rate = k_1).

0 1 . 4 Use the graph in **Figure 1** to calculate the value of k_1
Give the units of k_1

[3 marks]

$$\text{gradient} = (0.44 - 0.08) / (50 - 350) = 0.36 / (-300)$$

$$\text{rate} = k_1 = 0.36 / 300 = 1.2 \times 10^{-3} \text{ mol dm}^{-3} \text{ s}^{-1}$$

$$k_1 \quad 1.2 \times 10^{-3}$$

$$\text{Units} \quad \text{mol dm}^{-3} \text{ s}^{-1}$$

Turn over ►

0 1 . 5

A second reaction mixture is made at the same temperature. The initial concentrations of $\text{H}^+(\text{aq})$ and $\text{I}^-(\text{aq})$ in this mixture are both $0.500 \text{ mol dm}^{-3}$. There is a large excess of H_2O_2 .

In this reaction mixture, the rate depends only on the concentration of $\text{I}^-(\text{aq})$.

The results are shown in **Table 1**.

Table 1

Time / s	0	100	200	400	600	800	1000	1200
$[\text{H}^+]/\text{mol dm}^{-3}$	0.50	0.44	0.39	0.31	0.24	0.19	0.15	0.12

Plot these results on the grid in **Figure 2**. The first three points have been plotted.

[1 mark]

Figure 2

0 1 . 6

Draw a line of best fit on the grid in **Figure 2**.

[1 mark]

0 1 . 7

Calculate the rate of reaction when $[H^+] = 0.35 \text{ mol dm}^{-3}$
Show your working using a suitable construction on the graph in **Figure 2**.

[2 marks]

Tangent drawn to the curve at $[H^+] = 0.35 \text{ mol dm}^{-3}$ (Figure 2)

$$\text{gradient} = (0.45 - 0.20) / (660 - 60) = 0.25 / 600$$

$$\text{rate} = 4.2 \times 10^{-4} \text{ mol dm}^{-3} \text{ s}^{-1}$$

Rate 4.2×10^{-4} $\text{mol dm}^{-3} \text{ s}^{-1}$

Question 1 continues on the next page

Turn over ►

0 1 . 8 A general equation for a reaction is shown.

In aqueous solution, **A**, **B**, **C** and **D** are all colourless but **E** is dark blue.

A reagent (**X**) is available that reacts rapidly with **E**. This means that, if a small amount of **X** is included in the initial reaction mixture, it will react with any **E** produced until all of the **X** has been used up.

Explain, giving brief experimental details, how you could use a series of experiments to determine the order of this reaction with respect to **A**. In each experiment you should obtain a measure of the initial rate of reaction.

[6 marks]

Stage 1, preparation: using burettes / pipettes, measure known volumes of B and C and a small, fixed volume (amount) of X into one beaker.

Measure a known volume of A into a separate beaker. Stand both in a water bath so they are at the same constant temperature.

Stage 2, procedure: pour A into the mixture of B, C and X, swirl to mix and start a stopwatch at the moment of mixing.

Record the time taken for the dark blue colour of E to appear (this happens as soon as all of the X has been used up).

Repeat with different concentrations of A, by using different volumes of A made up to the same total volume with water. Keep the concentrations (volumes) of B and C, the amount of X, the total volume and the temperature the same in each experiment, so A is the only variable.

Stage 3, use of results: the blue colour appears when the same fixed amount of E has formed in each experiment, so 1/time is a measure of the initial rate.

Plot 1/time (rate) against the volume / concentration of A.

If 1/time stays constant (horizontal line) the reaction is zero order with respect to A. If the graph is a straight line through the origin

(doubling $[A]$ doubles the rate) it is first order. If doubling $[A]$ makes the rate four times faster (a curve, $\text{rate} \propto [A]^2$) it is second order.

Alternatively, plot $\log(1/\text{time})$ against $\log(\text{volume or concentration of } A)$: the gradient of this straight line gives the order with respect to A .

0 2

The elements sodium to sulfur in Period 3 all react with oxygen to form oxides.

0 2 . 1

Give an equation and **two** observations made for the reaction that occurs when sodium is heated in oxygen.

[2 marks]

Equation $4\text{Na} + \text{O}_2 \rightarrow 2\text{Na}_2\text{O}$

Observation 1 *Yellow / orange flame*

Observation 2 *White solid (powder / ash) formed*

0 2 . 2

Give an equation and **one** observation made for the reaction that occurs when phosphorus is heated in oxygen.

[2 marks]

Equation $4\text{P} + 5\text{O}_2 \rightarrow \text{P}_4\text{O}_{10}$

Observation *White flame (light) and white fumes / smoke*

0 2 . 3

The melting points of the highest oxides of the elements sodium to sulfur are shown in **Table 2**.

Table 2

	Highest oxide of					
	sodium	magnesium	aluminium	silicon	phosphorus	sulfur
Melting point/K	1548	3125	2345	1883	573	290

Explain the increase in melting point from sodium oxide to magnesium oxide.

[2 marks]

Mg²⁺ has a greater charge (2+ rather than 1+) and is smaller than

Na⁺, so it has a greater charge density.

So there is stronger electrostatic attraction between the oppositely

charged Mg²⁺ and O²⁻ ions (stronger ionic bonding), so more energy is

needed to overcome it.

0 2 . 4

Explain why the melting point of the oxide of silicon is much higher than that of the highest oxide of phosphorus.

[3 marks]

SiO₂ is giant covalent (macromolecular).

P₄O₁₀ is (simple) molecular.

Melting SiO₂ requires breaking many strong covalent bonds throughout the whole structure, which needs much more energy than overcoming the weak intermolecular forces (van der Waals' forces) between P₄O₁₀ molecules.

0 2 . 5

A sample of the highest oxide of phosphorus was prepared in a laboratory.

Describe a method for determining the melting point of the sample.
State how the result obtained could be used to evaluate its purity.

[3 marks]

Put a small amount of the dry, powdered sample into a capillary tube (sealed at one end) and place it in a melting point apparatus (or a Thiele tube / oil bath).

Heat slowly and gently near the melting point and record the temperature range over which the solid melts.

A pure sample melts sharply (over a narrow range) at the data book value of 573 K. A lower melting point and a broad melting range indicate the presence of impurities.

Turn over ►

0	3
---	---

Cyclohexene (boiling point = 83°C) can be prepared by the dehydration of cyclohexanol (boiling point = 161°C) using concentrated phosphoric acid.

A student prepared cyclohexene by placing 10 cm^3 of cyclohexanol (density = 0.96 g cm^{-3}) into a round-bottomed flask. 3 cm^3 of concentrated phosphoric acid were then carefully added to the flask. The student added a few anti-bumping granules and set up the apparatus shown in **Figure 3**.

Figure 3

- The student heated the mixture and collected the liquid that distilled at temperatures below 100°C
- The distillate was poured into a separating funnel and washed by shaking with sodium carbonate solution.
- Periodically, the separating funnel was inverted and the tap opened.
- The aqueous layer was discarded and the final organic product was dried using anhydrous calcium chloride.
- After the product was dried, the drying agent was removed by filtration under reduced pressure.

- 0 3 . 1 The student collected 5.97 g of cyclohexene in the experiment.

Calculate the percentage yield of cyclohexene.

[3 marks]

$$\text{mass of cyclohexanol} = 10 \times 0.96 = 9.6 \text{ g}$$

$$\text{moles of cyclohexanol} = 9.6 / 100.0 = 0.096 \text{ mol}$$

$$\text{max mass of cyclohexene} = 0.096 \times 82.0 = 7.87 \text{ g}$$

$$\% \text{ yield} = 5.97 / 7.87 \times 100 = 75.8\%, \text{ so } 76\%$$

Percentage yield 76 %

- 0 3 . 2 Describe a test-tube reaction, on the product, to show that the cyclohexanol had been dehydrated.
State what you would observe.

[2 marks]

Add a few drops of bromine water to the product and shake.

The bromine water turns from orange to colourless (decolourises).

- 0 3 . 3 Suggest why sodium carbonate solution was used to wash the distillate.

[1 mark]

To neutralise (react with and remove) the phosphoric acid, H_3PO_4 , present in the distillate.

- 0 3 . 4 Explain why it is important to open the tap of the separating funnel periodically.

[1 mark]

To release the pressure from the CO_2 gas produced, which would otherwise build up and could blow the stopper out.

Question 3 continues on the next page

Turn over ►

0 3 . 5

Give a property of anhydrous calcium chloride, other than its ability to absorb water, that makes it suitable as a drying agent in this preparation.

[1 mark]

It does not dissolve in, or react with, the cyclohexene.

0 3 . 6

Describe the apparatus used to remove the drying agent by filtration under reduced pressure. Your description of the apparatus can be either a labelled diagram **or** a description in words.

[2 marks]

Filter using a Buchner funnel containing a (flat) circle of filter paper, fitted with an airtight rubber bung into a Buchner (side-arm) flask, with the side-arm connected to a vacuum (water) pump.

0 3 . 7

A sample of cyclohexene has been contaminated with cyclohexanol. The cyclohexene can be separated from the cyclohexanol by column chromatography. Silica gel is used as the stationary phase and hexane as the mobile phase.

Explain why cyclohexene has a shorter retention time than cyclohexanol.

[2 marks]

Cyclohexene is less polar than cyclohexanol (cyclohexanol is polar, with an O-H group that can hydrogen bond to the silica).

So cyclohexene has a greater affinity for the non-polar mobile phase (hexane), while cyclohexanol has a greater affinity for the polar stationary phase (silica) and is held for longer.

0 3 . 8

Explain how an infrared spectrum would confirm that the cyclohexene obtained from the chromatography column did **not** contain any cyclohexanol.

[1 mark]

There would be no (broad) absorption at 3230 to 3550 cm^{-1} , which is due to the O-H (alcohol) bond.

13

Turn over for the next question

Turn over ►

0 4

A student carried out an experiment to find the temperature rise for a reaction between hydrochloric acid and sodium hydroxide solution.

- The student used a measuring cylinder to place 50 cm^3 of $0.400 \text{ mol dm}^{-3}$ hydrochloric acid into a glass beaker.
- The student recorded the temperature at one-minute intervals for three minutes.
- At the fourth minute the student added 50 cm^3 of $0.400 \text{ mol dm}^{-3}$ sodium hydroxide solution and stirred to mix the solutions, but did not record the temperature.
- The student recorded the temperature at one-minute intervals for a further eight minutes.

The results are shown in **Table 3**.

Table 3

Time / min	0	1	2	3	4	5	6	7	8	9	10	11	12
Temperature / °C	19.8	19.8	19.8	19.8		21.4	21.7	21.6	21.5	21.4	21.3	21.2	21.1

0 4 . 1

Plot a graph of temperature against time on the grid opposite.
Use your graph to find the temperature rise, ΔT , at the fourth minute.
Show your working on the graph by drawing suitable lines of best fit.

[5 marks]

At 4 minutes (from the extrapolated lines): $\Delta T = 21.9 - 19.8$

ΔT 2.1 °C

0 4 . 2

The uncertainty in each of the temperature readings from the thermometer used in this experiment was $\pm 0.1^\circ \text{C}$

Calculate the percentage uncertainty in the value for the temperature rise.

[1 mark]

uncertainty in $\Delta T = 2 \times 0.1 = 0.2^\circ \text{C}$

% uncertainty = $0.2 / 2.1 \times 100 = 9.5\%$

Percentage uncertainty 9.5%

0 4 . 3

Suggest a change to the experiment that would minimise heat loss.

[1 mark]

Replace the glass beaker with a polystyrene cup (insulate the beaker)

and use a lid.

Turn over ►

0 4 . 4

Suggest and explain another change to the experiment that would decrease the percentage uncertainty in the use of the same thermometer.

[2 marks]

Increase the magnitude of the temperature change by increasing the concentration of the acid and the alkali (e.g. use $0.800 \text{ mol dm}^{-3}$).

The $\pm 0.2 \text{ }^{\circ}\text{C}$ uncertainty is then a smaller percentage of the larger ΔT .

0 4 . 5

A second student completed an experiment to determine the enthalpy of neutralisation for the reaction between ethanedioic acid solution (HOOCCOOH) and potassium hydroxide solution.

The student added 25 cm^3 of 0.80 mol dm^{-3} ethanedioic acid solution to 75 cm^3 of 0.60 mol dm^{-3} potassium hydroxide solution.

The temperature increased by $3.2 \text{ }^{\circ}\text{C}$

Give an equation for the reaction between ethanedioic acid solution and potassium hydroxide solution.

Calculate the enthalpy change (ΔH) per mole of water formed in this reaction.

Assume that the specific heat capacity of the reaction mixture is $4.2 \text{ J K}^{-1} \text{ g}^{-1}$

Assume that the density of the reaction mixture is 1.00 g cm^{-3}

[5 marks]

Equation $\text{HOOC}\text{COOH} + 2\text{KOH} \rightarrow \text{K}_2\text{C}_2\text{O}_4 + 2\text{H}_2\text{O}$

$$q = mc\Delta T = 100 \times 4.2 \times 3.2 = 1344 \text{ J} = 1.344 \text{ kJ}$$

$$n(\text{HOOC}\text{COOH}) = 25 \times 0.80 / 1000 = 0.020 \text{ mol}$$

$$n(\text{KOH}) = 75 \times 0.60 / 1000 = 0.045 \text{ mol (KOH in excess)}$$

$$\text{moles of water formed} = 2 \times 0.020 = 0.040 \text{ mol}$$

$$\Delta H = -1.344 / 0.040 = -33.6 \text{ kJ mol}^{-1}$$

$$\Delta H \quad \underline{-33.6} \quad \text{kJ mol}^{-1}$$

0 4 . 6

In a similar experiment to that in Question 04.5, the enthalpy of neutralisation for the reaction between sulfuric acid and potassium hydroxide solution was found to be $-57.0 \text{ kJ mol}^{-1}$ per mole of water formed.

Suggest an explanation for the difference between this value and your answer to Question 04.5.

(If you were unable to obtain an answer to Question 04.5 you should assume a value of $-28.5 \text{ kJ mol}^{-1}$. This is **not** the correct answer.)

[2 marks]

Ethanedioic acid (HOOCCOOH) is a weak acid, so it is not fully dissociated, whereas H_2SO_4 is a strong acid and is fully dissociated.

Energy is needed to break the O–H bonds and complete the dissociation of the weak acid (dissociation is endothermic), so less energy is released per mole of water formed.

16

Turn over for Section B

Turn over ►

Section B

Answer **all** questions in this section.Only **one** answer per question is allowed.

For each answer completely fill in the circle alongside the appropriate answer.

CORRECT METHOD WRONG METHODS If you want to change your answer you must cross out your original answer as shown. If you wish to return to an answer previously crossed out, ring the answer you now wish to select as shown. You may do your working in the blank space around each question but this will not be marked.
Do **not** use additional sheets for this working.

A Thymol blue (pH range 1.2–2.8)

☐

B Bromophenol blue (pH range 3.0–4.6)

☒

C Phenol red (pH range 6.8–8.4)

☐

D Phenolphthalein (pH range 8.3–10.0)

☐

3 3 Lattice enthalpy values can be obtained from Born–Haber cycles and by calculations based on a perfect ionic model.

Which compound shows the greatest percentage difference between these two values?

[1 mark]

A CsF

☐

B CsI

☐

C LiF

☐

D LiI

☒

3	4
---	---

For this reaction at equilibrium, which combination of temperature and pressure would give the greatest equilibrium yield of products?

[1 mark]

A High pressure and high temperature

☐

B High pressure and low temperature

☐

C Low pressure and high temperature

☒

D Low pressure and low temperature

☐
