A-level CHEMISTRY

Paper 3

Friday 23 June 2023

Morning

Time allowed: 2 hours

Materials

For this paper you must have:

- the Periodic Table/Data Booklet, provided as an insert (enclosed)
- a ruler with millimetre measurements
- a scientific calculator, which you are expected to use where appropriate.

Instructions

- Use black ink or black ball-point pen.
- Fill in the boxes at the top of this page.
- Answer **all** questions.
- You must answer the questions in the spaces provided. Do **not** write outside the box around each page or on blank pages.
- If you need extra space for your answer(s), use the lined pages at the end of this book. Write the question number against your answer(s).
- All working must be shown.
- Do **all** rough work in this book. Cross through any work you do not want to be marked.

Information

- The marks for questions are shown in brackets.
- The maximum mark for this paper is 90.

Advice

- You are advised to spend 70 minutes on **Section A** and 50 minutes on **Section B**.

For Examiner's Use

Section A

Answer **all** questions in this section.

0 1

Ethyl ethanoate can be made by reacting ethanol with ethanoic acid in the presence of concentrated sulfuric acid.

Method

1. A mixture of ethanol, ethanoic acid, and concentrated sulfuric acid, with anti-bumping granules, is heated under reflux for 10 minutes.
2. The apparatus is rearranged for distillation.
3. The mixture is heated to collect the liquid that distills between 70 and 85 °C
4. The distillate is placed in a separating funnel. Aqueous sodium carbonate is added, and a stopper is placed in the funnel. The mixture is shaken, releasing pressure as necessary.
5. The lower aqueous layer is removed and the upper organic layer is placed in a small conical flask.
6. Anhydrous calcium chloride is added to the sample in the conical flask. The flask is shaken well and left for a few minutes.
7. The liquid from the flask is redistilled and the distillate is collected between 74 and 79 °C

0 1 . 1

State the role of concentrated sulfuric acid in this reaction.

[1 mark]

Catalyst

0 1 . 2

The reaction mixture is flammable.

Suggest how the reaction mixture should be heated in step 1.

[1 mark]

Use an electric heater (heating mantle) or a hot water bath, not a Bunsen burner (naked flame).

0 1 3

Figure 1 shows how a student set up the apparatus for reflux in step 1. You should assume that the apparatus is clamped correctly.

Figure 1

Identify **two** mistakes the student made in setting up the apparatus.

State the problem caused by each mistake.

[4 marks]

Mistake 1 There is a bung (stopper) in the top of the condenser.

Problem caused The apparatus is sealed, so pressure builds up as the mixture is heated and the bung could be forced out.

Mistake 2 The water goes the wrong way through the condenser: in at the top and out at the bottom.

Problem caused The condenser does not fill with cold water, so it does not cool enough and vapour (reactants and products) does not condense and escapes.

Turn over ►

0 1 . 4

State why sodium carbonate is added to the distillate in step 4.

Explain why there is a build-up of pressure in the separating funnel.

[2 marks]

To neutralise (react with and remove) the acid, i.e. the ethanoic acid and sulfuric acid in the distillate.

The acid reacts with sodium carbonate to produce carbon dioxide gas, which builds up in the stoppered funnel.

0 1 . 5

Give a reason why two layers form in the separating funnel.

Suggest why ethyl ethanoate forms the upper layer.

[2 marks]

Reason *Ethyl ethanoate is immiscible with (insoluble in) water.*

Suggestion *Ethyl ethanoate is less dense than water (lower density than the aqueous layer).*

0 1 . 6

State why anhydrous calcium chloride is added in step 6.

[1 mark]

It is a drying agent: it removes (absorbs) water from the ethyl ethanoate.

0 1 . 7

A student uses the method to prepare some ethyl ethanoate.

The student adds 10.0 cm³ of ethanol ($M_r = 46.0$) to 5.25 g of ethanoic acid ($M_r = 60.0$) and obtains 5.47 g of ethyl ethanoate ($M_r = 88.0$).

For ethanol, density = 0.790 g cm⁻³

Determine the limiting reagent.

Calculate the percentage yield of ethyl ethanoate.

[5 marks]

$$\text{mass of ethanol} = 10.0 \times 0.790 = 7.90 \text{ g}$$

$$\text{amount of ethanol} = 7.90 / 46.0 = 0.172 \text{ mol}$$

$$\text{amount of ethanoic acid} = 5.25 / 60.0 = 0.0875 \text{ mol}$$

1 : 1 ratio and $0.0875 < 0.172$, so ethanoic acid is limiting

Limiting reagent ethanoic acid

$$\text{max amount of ethyl ethanoate} = 0.0875 \text{ mol}$$

$$\text{max mass of ethyl ethanoate} = 0.0875 \times 88.0 = 7.70 \text{ g}$$

$$\% \text{ yield} = 5.47 / 7.70 \times 100 = 71.0\%$$

Percentage yield 71.0%

0 1 . 8

Suggest a reason why the percentage yield is **not** 100%.

[1 mark]

The reaction is an equilibrium (reversible), so it does not go to completion.

0 2

This question is about isomerism and the dehydration of alcohols.

Pentan-2-ol has the molecular formula $C_5H_{12}O$

0 2 . 1

Draw the **displayed** formula of an unbranched position isomer of pentan-2-ol that can be dehydrated to form a single alkene.

[1 mark]

0 2 . 2

Draw the **skeletal** formula of a chain isomer of pentan-2-ol that can be dehydrated to form a mixture of alkenes.

[1 mark]

0 2 . 3

Draw the structure of an unbranched functional group isomer of pentan-2-ol.

[1 mark]

0 2 . 4

Another isomer of pentan-2-ol is an alcohol that is **not** dehydrated when heated with concentrated sulfuric acid.

Draw the structure of this isomer.

[1 mark]

0 2 . 5

An incomplete mechanism for the dehydration of a compound is shown.

Complete the mechanism for this reaction by drawing two curly arrows on the intermediate.

Name the mechanism for this reaction.

[3 marks]

Elimination

0 2 . 6

An isomer of the final product can also form in the reaction in Question 02.5.

Draw the structure of this isomer.

[1 mark]

0 3

Endomorphin-2 is a peptide with the amino acid sequence shown.

Each amino acid is represented by a three-letter abbreviation.

Tyr = tyrosine Pro = proline Phe = phenylalanine

Figure 2 shows part of the structure of endomorphin-2, showing the Tyr-Pro-Phe-part of the molecule.

Figure 2

0 3 . 1

The -NH_2 at the end of the amino acid sequence of endomorphin-2 shows that the terminal functional group is an amide, not an acid.

Complete the structure of endomorphin-2 in **Figure 2**.

[2 marks]

0 3 . 2

Use the structure in **Figure 2** to draw the skeletal formula of proline, Pro.

[1 mark]

A student hydrolyses a sample of endomorphin-2 to break it down into its constituent amino acids.

The student analyses the resulting mixture by thin-layer chromatography, TLC.

0 3 . 3

State a reagent and the conditions needed for the hydrolysis.

[2 marks]

Reagent Hydrochloric acid, HCl(aq)

Conditions Heat under reflux

0 3 . 4

Figure 3 shows the apparatus used for the TLC.

Figure 3

There is a piece of the apparatus missing from **Figure 3**. This omission will result in an inaccurate chromatogram.

Identify the missing piece of the apparatus.

State and explain why this piece of the apparatus is needed.

[3 marks]

Missing piece A lid (cover) on the beaker

Explanation It stops the volatile solvent evaporating from the beaker, so the air in the beaker is saturated with solvent vapour.

This reduces evaporation of solvent from the plate, so the solvent can rise up the plate.

Turn over ►

0 3 . 5

State why the amino acids separate on the TLC plate.

[1 mark]

Each amino acid has a different balance between its solubility in the mobile phase (solvent) and its attraction to (retention on) the stationary phase (silica).

When the solvent has risen up the TLC plate, the student removes the plate from the beaker and sprays it with a developing agent.

Figure 4 shows the result.

Figure 4

0 3 . 6

Name a suitable developing agent.

State why the developing agent is needed.

[2 marks]

Name *Ninhydrin*

Why needed *Amino acids are colourless, so it is needed to make the amino acid spots visible.*

03.7

Determine the R_f value for Tyr.

[1 mark]

$$R_f = \text{distance moved by Tyr} / \text{distance moved by solvent}$$
$$= 4.75 \text{ cm} / 8.75 \text{ cm} = 0.54$$

 R_f 0.54

12

Turn over for the next question

Turn over ►

0 4

A student is given two aqueous solutions, **L** and **M**, that both contain iron salts.

The student does a series of tests on the solutions.

Table 1 shows these tests and the observations.

Table 1

Test	Observations with L	Observations with M
Add ammonia solution slowly until in excess.	A red-brown precipitate forms that is insoluble in excess.	A green precipitate forms that is insoluble in excess.
Add sodium carbonate solution.	A red-brown precipitate forms. Effervescence is seen.	A green precipitate forms.
Add dilute nitric acid and then divide into two portions.	No change is seen.	No change is seen.
Add barium chloride solution to the first portion.	No change is seen.	A white precipitate forms.
Add silver nitrate solution to the second portion.	A white precipitate forms.	No change is seen.

Identify **L** and **M** using the results in **Table 1**.

In your answer:

- identify **all** precipitates
- explain why effervescence is seen in the reaction of sodium carbonate with **L** but **not** with **M**
- give ionic equations for **all** reactions.

[6 marks]

L is iron(III) chloride, FeCl_3 , and M is iron(II) sulfate, FeSO_4 .

Ammonia: the red-brown precipitate with L is $\text{Fe}(\text{H}_2\text{O})_3(\text{OH})_3$ (iron(III) hydroxide):

The green precipitate with M is $\text{Fe}(\text{H}_2\text{O})_4(\text{OH})_2$ (iron(II) hydroxide):

Sodium carbonate: L gives the red-brown precipitate $\text{Fe}(\text{H}_2\text{O})_3(\text{OH})_3$ and the effervescence is carbon dioxide gas:

M gives a green precipitate of iron(II) carbonate, FeCO_3 :

Effervescence is seen with L but not M because $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$ is more acidic than $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$. The Fe^{3+} ion is smaller and has a higher charge, so it has a greater charge density and is more polarising. It weakens the O–H bonds in the water ligands, so $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$ is a better proton donor and is acidic enough to react with carbonate ions to release CO_2 . $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$ is not acidic enough, so M forms FeCO_3 instead.

Barium chloride: the white precipitate with M is barium sulfate, BaSO_4 , so M contains sulfate ions:

Silver nitrate: the white precipitate with L is silver chloride, AgCl , so L contains chloride ions:

The dilute nitric acid is added first to remove carbonate or hydroxide ions that would also give precipitates.

0 5

The molar enthalpy of vaporisation (ΔH_{vap}) of a liquid is the enthalpy change when one mole of liquid is converted to vapour at the boiling point of the liquid.

A student does an experiment to determine ΔH_{vap} for water.

The student:

- places a large beaker on a balance
- pours 500 cm³ of water into the beaker
- uses a 2.4 kW heater to raise the temperature of the water to 100 °C
- records the mass of the beaker and hot water
- uses the 2.4 kW heater to boil the water for 100 s
- records the mass of the beaker and remaining water.

The loss in mass is 103 g

0 5

. 1

Calculate ΔH_{vap} for water.

[1 kW = 1 kJ s⁻¹]

[3 marks]

$$\text{energy transferred} = 2.4 \text{ kJ s}^{-1} \times 100 \text{ s} = 240 \text{ kJ}$$

$$\text{amount of water vaporised} = 103 / 18.0 = 5.72 \text{ mol}$$

$$\Delta H_{\text{vap}} = \text{energy transferred} / \text{amount of water}$$

$$= 240 / 5.72 = +41.9 \text{ kJ mol}^{-1}$$

$$\Delta H_{\text{vap}} \underline{\hspace{1cm} +41.9 \hspace{1cm}} \text{ kJ mol}^{-1}$$

Table 2 shows some data about three compounds that **all** contain the same number of electrons.

Table 2

Compound	$\text{CH}_3\text{CH}_2\text{OH}$	$\text{CH}_3\text{CH}_2\text{NH}_2$	CH_3OCH_3
Boiling point / K	352	290	248

0 5 . 2

All three compounds in **Table 2** are polar.

Ethanol is the most polar and ethylamine is the least polar.

Explain why **all** three molecules are polar and why ethylamine is the least polar.

In your answer refer to the shapes around, and relative electronegativities of, the most electronegative atoms.

[4 marks]

O and N are more electronegative than C and H, so all three molecules have polar bonds.

O in $\text{CH}_3\text{CH}_2\text{OH}$ and CH_3OCH_3 has 2 bonding pairs and 2 lone pairs, so the shape around O is bent (V-shaped). N in $\text{CH}_3\text{CH}_2\text{NH}_2$ has 3 bonding pairs and 1 lone pair, so it is (trigonal) pyramidal.

These shapes are not symmetrical, so the dipoles do not cancel and all three molecules are polar.

O is more electronegative than N, so the bonds to N are less polar and ethylamine is the least polar.

0 5 . 3

Explain the trend in the boiling points of the three compounds.

Refer to the intermolecular forces in **all** three compounds in your answer.

[3 marks]

Ethanol and ethylamine both have hydrogen bonding between molecules, but methoxymethane has no H bonded to O, so it only has (permanent) dipole-dipole forces.

Hydrogen bonds are stronger than dipole-dipole forces, so methoxymethane has the lowest boiling point.

Hydrogen bonding is stronger in ethanol than in ethylamine because O is more electronegative than N, so ethanol has the highest boiling point.

10

Turn over ►

0 6

Calcium hydroxide is almost insoluble in water, but it reacts with dilute hydrochloric acid.

A student adds 100 cm³ of 0.100 mol dm⁻³ hydrochloric acid to 0.600 g of solid calcium hydroxide.

0 6 . 1

Show, by calculation, that the calcium hydroxide is in excess.

[2 marks]

$$\text{amount of HCl} = 100 \times 0.100 / 1000 = 0.0100 \text{ mol}$$

$$\text{amount of Ca(OH)}_2 = 0.600 / 74.1 = 0.00810 \text{ mol}$$

$$\text{Ca(OH)}_2 \text{ needed for } 0.0100 \text{ mol HCl} = 0.0100 / 2 = 0.00500 \text{ mol}$$

$$0.00810 \text{ mol} > 0.00500 \text{ mol needed, so Ca(OH)}_2 \text{ is in excess}$$

0 6 . 2

The final mixture contains a saturated solution of Ca(OH)₂ at 293 K

At 293 K

- the solubility of Ca(OH)₂ in this solution is 0.400 g dm⁻³
- $K_w = 6.80 \times 10^{-15} \text{ mol}^2 \text{ dm}^{-6}$

Calculate the pH of this solution.

Give your answer to two decimal places.

[5 marks]

$$[\text{Ca(OH)}_2] = 0.400 / 74.1 = 0.00540 \text{ mol dm}^{-3}$$

$$[\text{OH}^-] = 2 \times 0.00540 = 0.0108 \text{ mol dm}^{-3}$$

$$[\text{H}^+] = K_w / [\text{OH}^-] = 6.80 \times 10^{-15} / 0.0108$$

$$= 6.30 \times 10^{-13} \text{ mol dm}^{-3}$$

$$\text{pH} = -\log[\text{H}^+] = -\log(6.30 \times 10^{-13}) = 12.20$$

pH 12.20

7

Section B

Answer **all** questions in this section.Only **one** answer per question is **allowed**.For each answer completely **fill** in the circle alongside the appropriate answer.

CORRECT METHOD

WRONG METHODS

If you want to change your answer you must cross out your original answer as shown.

If you wish to return to an answer previously crossed out, ring the answer you now wish to select as shown.

You may do your working in the **blank** space around each question but this **will** not be marked.
Do **not** use additional sheets for this working.
