Paper 2

Time allowed: 2 hours

Materials

For this paper you must have:

- a pencil and a ruler
- a scientific calculator
- a Data and Formulae Booklet
- a protractor.

Instructions

- Use **black ink** or **black ball-point pen**.
- **Fill** in the boxes at the top of this page.
- Answer **all** questions.
- You must answer the questions in the spaces provided. Do not write outside the box around each page or on blank pages.
- If you need extra space for your answer(s), use the lined pages at the end of this book. Write the question number against your answer(s).
- Do **all** rough work in this book. Cross through any work you do not want to be marked.
- Show **all** your working.

Information

- The marks for questions are shown in brackets.
- The maximum mark for this paper is 85.
- You are expected to use a scientific calculator where appropriate.
- A Data and Formulae Booklet is provided as a loose insert.

Section AAnswer **all** questions in this section.**0 1**

A capacitor of capacitance 63 pF is made from two parallel metal plates separated by an air gap.

The capacitor is charged so that it stores a charge of 7.6×10^{-10} C; it is then isolated.

A sheet of mica of dielectric constant 6.0 is inserted between the plates so that it completely fills the space between them. The mica does not discharge the capacitor and does not change the separation of the plates.

0 1 . 1

Explain what is meant by a dielectric constant of 6.0

[1 mark]

The permittivity of the mica is 6.0 times the permittivity of free space,

i.e. $\epsilon_r = \epsilon$ (permittivity of mica) / $\epsilon_0 = 6.0$

0 1 . 2

Mica is made up of polar molecules. As the mica is inserted, the capacitance of the capacitor changes.

Explain how the polar molecules cause this change in capacitance.

[3 marks]

There is an electric field between the charged plates. The polar molecules rotate and align with their positive ends facing the negative plate (and negative ends facing the positive plate).

This produces an opposing electric field between the plates, which reduces the overall electric field between the plates.

So the pd V between the plates decreases, but the charge Q stays the same because the capacitor is isolated, so the capacitance $C = Q/V$ increases.

0 1 . 3

Calculate the difference between the initial energy stored by the capacitor and the energy stored when the mica has been fully inserted.

[3 marks]

$$Q \text{ stays the same} = 7.6 \times 10^{-10} \text{ C, new } C = 6 \times 63 \text{ pF} = 378 \text{ pF}$$

$$E = Q^2/2C$$

$$\text{initial } E = (7.6 \times 10^{-10})^2 / (2 \times 63 \times 10^{-12}) = 4.58 \times 10^{-9} \text{ J}$$

$$\text{final } E = (7.6 \times 10^{-10})^2 / (2 \times 378 \times 10^{-12}) = 7.64 \times 10^{-10} \text{ J}$$

$$\text{difference} = 4.58 \times 10^{-9} - 7.64 \times 10^{-10} = 3.82 \times 10^{-9} \text{ J}$$

$$\text{energy difference} = \underline{3.8 \times 10^{-9}} \text{ J}$$

Question 1 continues on the next page

Turn over ►

Figure 1 shows the structure of a variable capacitor used for measuring angular movement. The capacitor consists of two semicircular metal plates. These plates are parallel and are separated by an air gap.

Figure 1

To vary the capacitance, one of the plates is rotated through an angle θ using the spindle. The other plate remains fixed.

0 1 . 4

Sketch a graph on **Figure 2** to show how the capacitance C varies with θ as the spindle is turned through 360° .
When θ is 0° , the plates completely overlap.

[2 marks]

Figure 2

0 1 . 5

In one situation, the variable capacitor is too large for the available space.

The same maximum capacitance is required using plates that have half the diameter of the original capacitor.

Explain, with numerical detail, **two** ways in which this can be achieved.

[3 marks]

1 *Fill the gap between the plates with a dielectric of relative permittivity $\epsilon_r = 4$ (keeping the same separation). Halving the diameter makes the area $1/4$ of the original, and $C = A\epsilon_0\epsilon_r/d$, so ϵ_r must be 4 times larger.*

2 *Keep the air gap but reduce the separation of the plates to $1/4$ of the original. Since $C \propto A/d$, reducing d by a factor of 4 cancels the factor of 4 decrease in area, so the maximum C is unchanged.*

0 2

The Global Positioning System (GPS) uses satellites to support navigation on Earth.

0 2 . 1

One GPS satellite is in a circular orbit at a height h above the surface of the Earth. The Earth has mass M and radius R .

Show that the angular speed ω of the satellite is given by

$$\omega = \sqrt{\frac{GM}{(R+h)^3}}$$

[2 marks]

Gravitational force provides the centripetal force ($r = R + h$):

$$GMm / r^2 = m\omega^2 r$$

$$\omega^2 = GM / r^3 = GM / (R + h)^3$$

$$\text{so } \omega = \sqrt{GM / (R + h)^3}$$

0 2 . 2

Calculate the orbital period of the satellite when h equals 2.02×10^7 m.

[2 marks]

$$r = R + h = 6.37 \times 10^6 + 2.02 \times 10^7 = 2.657 \times 10^7 \text{ m}$$

$$\omega = \sqrt{6.67 \times 10^{-11} \times 5.97 \times 10^{24} / (2.657 \times 10^7)^3}$$

$$\omega = 1.457 \times 10^{-4} \text{ rad s}^{-1}$$

$$T = 2\pi / \omega = 2\pi / 1.457 \times 10^{-4} = 4.31 \times 10^4 \text{ s}$$

orbital period = 4.31×10^4 s

0 2 . 3

Figure 3 shows the orbital plane of the satellite inclined at an angle to the equator. **X**, **Y** and **Z** are locations on the Earth.

X is at the North Pole, **Y** is on a high mountain and **Z** is on the equator.

Figure 3

The satellite is to be launched from one of the locations.

State and explain which launch site **X**, **Y** or **Z** minimises the amount of fuel required to send the satellite into its orbit.

[2 marks]

Launch from Z, on the equator. At this position the satellite already has the largest initial speed (kinetic energy) from the Earth's rotation, because Z is furthest from the axis of rotation. So less extra kinetic energy needs to be supplied by the fuel.

Question 2 continues on the next page

Turn over ►

0 2 . 4

The satellite has a mass of 1630 kg.

Calculate the gravitational potential energy of the satellite when in the orbit in Question 02.2.

[2 marks]

$$E_p = -GMm / r \quad (r = 2.657 \times 10^7 \text{ m})$$

$$E_p = -(6.67 \times 10^{-11} \times 5.97 \times 10^{24} \times 1630) / 2.657 \times 10^7$$

$$E_p = -2.44 \times 10^{10} \text{ J}$$

gravitational potential energy = -2.44×10^{10} J

0 2 . 5

A different satellite is in a higher circular orbit.

Explain how the linear speed of this satellite compares with the linear speed of the satellite in Question 02.1.

[2 marks]

The linear speed is smaller in the higher orbit.

$GMm/r^2 = mv^2/r$, so $v = \sqrt{GM/r}$, i.e. $v \propto 1/\sqrt{r}$. Since r is larger for the higher orbit, v is smaller (also $v = r\omega = r\sqrt{GM/r^3} = \sqrt{GM/r}$).

0 3

Figure 4 and **Figure 5** show apparatus used in an experiment to confirm the distribution of atom speeds in a gas at a particular temperature.

The oven contains an ideal gas kept at a constant temperature. Atoms of the gas emerge from the oven and some pass through the narrow slit **S** in a rapidly rotating drum. The drum is in a vacuum.

0 3 . 1

Explain why the drum must be in a vacuum.

[1 mark]

If the drum were not in a vacuum, the gas atoms would collide with air molecules, changing their direction and speed, so the speed distribution would be changed and atoms would not travel straight across to the detector.

One atom leaves the oven, enters the drum through **S** and travels in a straight line across the drum.

In the time taken for the atom to move from **S** to the detector **AB**, the drum rotates through 45° . The atom hits the detector at point **C**, as shown in **Figure 5**.

drum diameter = distance from **S** to **A** = 0.500 m
drum rotational speed = 120 revolutions per second

0 3 . 2 Show that the atom is moving at a speed of about 500 m s^{-1} .

[2 marks]

$$\text{Time for 1 revolution} = 1/120 \text{ s} = 8.33 \times 10^{-3} \text{ s}$$

$$45^\circ = 1/8 \text{ revolution, so } t = 8.33 \times 10^{-3} / 8 = 1.04 \times 10^{-3} \text{ s}$$

The atom travels the diameter, 0.500 m, in this time:

$$\text{speed} = \text{distance} / \text{time} = 0.500 / 1.04 \times 10^{-3}$$

$$\text{speed} = 480 \text{ m s}^{-1}, \text{ which is about } 500 \text{ m s}^{-1}$$

0 3 . 3 The speed of the atom in Question **03.2** is equal to c_{rms} , the root mean square speed of the atoms of the gas in the oven.
The molar mass of the gas is $0.209 \text{ kg mol}^{-1}$.

Calculate the temperature of the gas in the oven.

[3 marks]

$$\text{mass of one atom } m = 0.209 / 6.02 \times 10^{23} = 3.47 \times 10^{-25} \text{ kg}$$

$$\frac{1}{2}m(c_{\text{rms}})^2 = (3/2)kT, \text{ so } T = m(c_{\text{rms}})^2 / 3k$$

$$T = 3.47 \times 10^{-25} \times 480^2 / (3 \times 1.38 \times 10^{-23})$$

$$T = 1930 \text{ K}$$

temperature = 1930 K

Question 3 continues on the next page

Turn over ►

0 3 . 4

The oven temperature is kept constant during the experiment but the pressure in the oven decreases as atoms leave through the exit hole.

Explain, using the kinetic theory, why the pressure decreases.

[2 marks]

Pressure is due to the atoms colliding with the oven walls and changing momentum.

As atoms leave there are fewer atoms (N decreases), so there are fewer collisions with the walls per second.

T is constant, so c_{rms} and the average momentum change per collision stay the same, so the total rate of change of momentum on the walls falls and the pressure drops ($pV = (1/3)Nm(c_{rms})^2$, so $p \propto N$).

0 3 . 5

The pressure of gas in the oven is initially 5.0×10^4 Pa.

The volume of the oven is $2.7 \times 10^{-2} \text{ m}^3$.

During the experiment the pressure in the oven decreases to 4.5×10^4 Pa.

Calculate, in mol, the amount of gas that has emerged from the oven.

[1 mark]

$pV = nRT$, so the amount leaked $n = V(p_1 - p_2) / RT$

$n = 2.7 \times 10^{-2} \times (5.0 \times 10^4 - 4.5 \times 10^4) / (8.31 \times 1930)$

$n = 8.42 \times 10^{-3} \text{ mol}$

amount of gas = 8.42×10^{-3} mol

0 3 . 6

Atoms enter the drum every time **S** passes the exit hole. The detector darkens at the point where an atom strikes it.

After a time, the detector is removed from the drum.

Figure 6 shows the appearance of the detector.

Figure 6

A new detector is placed in the drum and the experiment is repeated with a new sample of the same gas at a higher temperature.

Describe and explain the appearance of this detector when the experiment is repeated.

[2 marks]

At the higher temperature the atoms move faster (higher c_{rms}), so they cross the drum in less time and the drum does not turn as far before they hit the detector.

So the darkest area (maximum darkness) will be closer to A than before.

Also, more atoms will pass through S as more atoms leave the oven per second, so the dark patch will be darker.

11

0 4

Figure 7 shows a search coil positioned on the axis of an electromagnet, with the plane of the search coil perpendicular to the axis. A magnetic field is produced by a constant current in the electromagnet. Assume that the magnetic flux density inside the search coil is uniform.

Figure 7

The distance between the search coil and the end of the electromagnet is x . **Figure 8** shows how the magnetic flux density B of the field varies with x .

Figure 8

The search coil has 200 turns and a cross-sectional area of $3.5 \times 10^{-5} \text{ m}^2$.

0 4 . 1

The search coil is placed at $x = 0.070 \text{ m}$.

Show that the magnetic flux linkage through the search coil is about $5 \times 10^{-4} \text{ Wb}$.

[2 marks]

From Figure 8, at $x = 0.070 \text{ m}$, $B = 0.070 \text{ T}$

flux linkage $N\Phi = BAN = 0.070 \times 3.5 \times 10^{-5} \times 200$

$N\Phi = 4.9 \times 10^{-4} \text{ Wb turns}$, which is about $5 \times 10^{-4} \text{ Wb}$

Question 4 continues on the next page

Turn over ►

The search coil is now moved at a constant speed of 0.80 m s^{-1} along the axis so that x is increasing. An emf is induced across the terminals of the search coil.

0 4 . 2

Explain what happens to the value of the emf as the search coil moves.

[2 marks]

As the coil moves, the magnetic flux through the coil changes, so there is a rate of change of flux linkage, which induces an emf.

By Faraday's law the emf is proportional to the rate of change of flux linkage. As x increases, the B against x graph gets less steep, so at constant speed the flux changes more slowly and the magnitude of the emf decreases.

0 4 . 3

The search coil passes through the position where $x = 0.10 \text{ m}$.

Deduce whether the emf can exceed 5 mV for values of x greater than 0.10 m .

[4 marks]

Tangent drawn on Figure 8 at $x = 0.10 \text{ m}$:

$$\text{gradient } \Delta B / \Delta x = 0.095 / 0.137 = 0.693 \text{ T m}^{-1}$$

$$\text{Faraday's law: } \text{emf} = N \Delta(BA) / \Delta t = NA(\Delta B / \Delta x)v$$

$$\text{emf} = 200 \times 3.5 \times 10^{-5} \times 0.693 \times 0.80$$

$$\text{emf} = 3.9 \times 10^{-3} \text{ V} = 3.9 \text{ mV at } x = 0.10 \text{ m}$$

For x greater than 0.10 m the gradient of the graph is smaller, so the emf at $x = 0.10 \text{ m}$ is the maximum in this range.

So No: the emf cannot exceed 5 mV for $x > 0.10 \text{ m}$.

0 5

Figure 9 shows a cyclotron. A proton is released from rest and is accelerated each time it reaches the gap between two horizontal 'dees' D_1 and D_2 . Between these accelerations the proton moves at constant speed. A vertical magnetic field of flux density B acts over the dees so that the proton follows a semicircular path in each dee.

The dees are connected to an alternating potential difference (pd). This pd is adjusted so that the proton is always accelerated by the peak electric field as it crosses the gap between the dees.

Figure 9

0 5 . 1

Explain why the proton travels in a semicircular path in a dee.

[2 marks]

The force on the proton is due to the uniform magnetic field ($F = Bev$), which is constant in size and always at 90° to the proton's direction of travel (velocity).

This force provides the centripetal force, so the proton moves in a circular path, and it travels half a circle in the dee before reaching the gap, so the path is semicircular.

Question 5 continues on the next page

Turn over ►

0 5 . 2

The peak pd of the alternating supply is 10.0 kV. The proton leaves the cyclotron with kinetic energy of 14 MeV.

Determine the number of times the proton moves across the gap before it leaves the cyclotron.

[1 mark]

Each crossing: 1 proton through 10.0 kV gains 10 000 eV

number of crossings = 14 MeV / 10 000 eV

$$= 14 \times 10^6 / 1.0 \times 10^4 = 1400$$

number of times = 1400

The radius of the outermost semicircular path of the proton is R and the proton leaves with a maximum kinetic energy E_k .

0 5 . 3

Show that E_k is given by

$$E_k = \frac{e^2 B^2 R^2}{2m_p}$$

[3 marks]

Magnetic force = centripetal force: $F = Bev$ and $F = m_p v^2 / R$

$$Bev = m_p v^2 / R, \text{ so } v = eBR / m_p$$

$$E_k = \frac{1}{2} m_p v^2 = \frac{1}{2} m_p (eBR / m_p)^2$$

$$E_k = e^2 B^2 R^2 / 2m_p$$

0 5 4

A hospital decides to purchase a cyclotron in order to manufacture its own radioactive isotopes using high-speed protons.

The required minimum kinetic energy of the emerging protons is 11 MeV.

The cost of a cyclotron is approximately proportional to $E_k^{1.5}$.

The cost of a 10 MeV cyclotron is about £2.3 million.

Table 1 gives information for three cyclotrons **X**, **Y** and **Z**.

Table 1

Cyclotron	B / T	R / m
X	1.3	0.38
Y	1.1	0.50
Z	0.5	0.60

Deduce which cyclotron **X**, **Y** or **Z** will satisfy the energy requirement for the lowest cost.

Go on to determine the approximate cost of this cyclotron.

[4 marks]

Use $E_k = e^2 B^2 R^2 / 2m_p$

X: $E_k = (1.6 \times 10^{-19})^2 \times 1.3^2 \times 0.38^2 / (2 \times 1.67 \times 10^{-27})$

$E_k = 1.87 \times 10^{-12} J = 11.7 \text{ MeV}$, just above 11 MeV, so X is OK

Y: $B^2 R^2$ is greater, $E_k = 2.32 \times 10^{-12} J = 14.5 \text{ MeV}$ (more than needed, so it costs more)

Z: $E_k = 6.89 \times 10^{-13} J = 4.3 \text{ MeV}$, less than 11 MeV, so not suitable

So X satisfies the requirement at the lowest cost.

$\text{cost} \propto E_k^{1.5}$; $\text{cost} = £2.3 \text{ million} \times (11.7 / 10)^{1.5} = £2.9 \text{ million}$

cyclotron = X

cost = £2.9 million

10

Turn over ►

0 6 . 1

Explain, in terms of binding energy, why energy can be released when two nuclei undergo nuclear fusion.

[2 marks]

The binding energy per nucleon increases when a nucleus is formed by fusion, so the binding energy of the nucleus formed is greater than the total binding energy of the two original nuclei.

So the total mass of the two nuclei is more than the mass of the fusion product, and this mass difference is released as energy ($E = mc^2$).

0 6 . 2

During the collapse of a supermassive star, helium-3 and oxygen-17 fuse to release energy. The equation for this reaction is

Table 2 gives data for these nuclei.

Table 2

Nucleus	Mass / u
${}^3_2\text{He}$	3.01603
${}^{17}_8\text{O}$	16.99913
${}^{20}_{10}\text{Ne}$	19.99244

Calculate, in J, the energy released when this reaction occurs.

[2 marks]

$$\Delta m = (3.01603 + 16.99913) - 19.99244 = 0.02272 \text{ u}$$

$$\Delta m = 0.02272 \times 1.661 \times 10^{-27} = 3.774 \times 10^{-29} \text{ kg}$$

$$E = mc^2 = 3.774 \times 10^{-29} \times (3.00 \times 10^8)^2 = 3.40 \times 10^{-12} \text{ J}$$

energy released = 3.40×10^{-12} J

0 6 . 3

One model of nuclear fusion suggests that fusion happens when nuclei touch.

Initially the helium nucleus and oxygen nucleus are separated so that the force between them is negligible. They move towards each other until they fuse. Fusion occurs when their centres are separated by a distance of $5.1 \times 10^{-15} \text{ m}$.

Figure 10 shows the initial positions and final positions of the nuclei.

Figure 10

Calculate the total change in electrostatic potential energy between the initial positions and final positions of the nuclei.

[2 marks]

$$E_p = Qq / 4\pi\epsilon_0 r \quad (E_p \approx 0 \text{ initially}), Q = 2e, q = 8e$$

$$E_p = 2 \times 8 \times (1.60 \times 10^{-19})^2 / (4\pi \times 8.85 \times 10^{-12} \times 5.1 \times 10^{-15})$$

$$\text{change in } E_p = 7.2 \times 10^{-13} \text{ J (increase)}$$

change in electrostatic potential energy = 7.2×10^{-13} J

Question 6 continues on the next page

Turn over ►

06.4

${}^3_2\text{He}$ can undergo fusion reactions with either ${}^{34}_{16}\text{S}$ or ${}^{17}_8\text{O}$ at the same temperature in a star.

The nucleus has properties that depend on its proton number and its nucleon number. These properties affect the fusion reaction.

Discuss, for this star, how these properties affect the rate of fusion of ${}^{34}_{16}\text{S}$ with ${}^3_2\text{He}$ compared to the rate of fusion of ${}^{17}_8\text{O}$ with ${}^3_2\text{He}$.

[3 marks]

Sulfur has proton number 16, double that of oxygen (8), so its nucleus has double the charge. This increases the repulsion and the gain in potential energy (force) needed to bring the nuclei together.

So fusion of sulfur with helium needs greater kinetic energy (a higher temperature), so at the same temperature this decreases the rate of fusion.

Sulfur has a larger nucleon number (34 compared to 17), so the sulfur nucleus has a larger radius than oxygen ($R \propto A^{1/3}$). The separation for fusion is larger, so smaller kinetic energy is needed, which increases the rate of fusion.

Two charged particles **P** and **Q** are separated by a distance of 120 mm. **X** is a point on the line between **P** and **Q** where the electric potential is zero.

What is the distance from **P** to **X**?

[1 mark]

A 40 mm

☐

B 48 mm

☐

C 60 mm

☐

D 72 mm

☒

1 8

An isolated spherical conductor is charged. The conductor has a radius R and an electric potential V . The electric field strength at its surface is E .

Point **T** is a distance $2R$ from the surface.

What are the electric field strength and electric potential at **T**?

[1 mark]

	Electric field strength	Electric potential	
A	$\frac{E}{2}$	$\frac{V}{4}$	☐
B	$\frac{E}{3}$	$\frac{V}{9}$	☐
C	$\frac{E}{4}$	$\frac{V}{2}$	☐
D	$\frac{E}{9}$	$\frac{V}{3}$	☒

1 9 **O** is the centre of a negatively charged sphere.

K and **L** are two points at a distance r_1 from **O**.
M and **N** are two points at a distance r_2 from **O**.

Which statement is true?

[1 mark]

- A** The work done moving an electron from **M** to **K** is the same as that done moving an electron from **K** to **L**. ☐
- B** The work done moving a positron from **K** to **M** is the same as that done moving an electron from **K** to **M**. ☐
- C** No work is done moving an electron from **M** to **N**. ☒
- D** No work is done moving a positron from **L** to **N**. ☐

The capacitor in the circuit is initially uncharged.
The switch is closed at time $t = 0$

Which pair of graphs shows how the potential difference V across the capacitor and the current I in the circuit change with time t ?

[1 mark]**A****B****C****D****A****B****C****D**

2 1

A short copper rod **R** is placed on a pair of thick horizontal parallel copper rails. A horizontal magnetic field exists in the direction shown by the dashed arrows. The diagram shows the apparatus when viewed from directly above.

When switch **S** is closed, **R** will tend to

[1 mark]

- A** lift upwards away from the rails.
- B** move to the left.
- C** move to the right.
- D** be pressed downwards onto the rails.

2 2

The diagram shows a square coil with its plane parallel to a uniform magnetic field.

The coil always remains within the magnetic field.

There are four possible changes to the position of the coil:

- moving it to the left
- moving it towards **Y**
- rotating it about the axis **YY'**
- rotating it about an axis **Z** that is at its centre and perpendicular to the plane of the coil.

How many of these changes will result in an induced emf in the coil while the change occurs?

[1 mark]

A one ☒

B two ☐

C three ☐

D four ☐

2 3

Mains electricity is rated 230 V in the UK.

Which is correct?

[1 mark]

A The mean voltage is 163 V. ☐

B The peak voltage is 230 V. ☐

C The root mean square voltage is 325 V. ☐

D The peak-to-peak voltage is 650 V. ☒

2 4

In a resistor of resistance R , a steady current I dissipates a power P .

In a resistor of resistance $\frac{R}{2}$ there is an alternating current of root mean square value $3I$.

What is the mean power dissipated in the resistor of resistance $\frac{R}{2}$?

[1 mark]**A** $9P$ ☐**B** $\frac{9}{2}P$ ☒**C** $\frac{9}{4}P$ ☐**D** $\frac{3}{2}P$ ☐**2 5**

The primary winding of a transformer has 200 turns and the secondary winding has 1600 turns.

A root mean square (rms) alternating voltage of 25 V is applied to the primary winding causing a primary rms current of 4.0 A. The transformer is 90% efficient.

What are the rms values of the secondary voltage and the secondary current?

[1 mark]

	Secondary voltage / V	Secondary current / A	
A	200	0.50	☐
B	200	0.45	☒
C	180	0.50	☐
D	3.1	29.0	☐

2 6

The diagram shows the path of a proton being deflected by the nucleus of an atom. Point **P** is the position of the proton when it is closest to the nucleus.

What is **not** true about the proton along its path at **P**?

[1 mark]

- A** Its rate of change of momentum is at a minimum. ☒
- B** Its kinetic energy is at a minimum. ☐
- C** Its potential energy is at a maximum. ☐
- D** Its acceleration is at a maximum. ☐

2 7

The diagram shows an area of 0.10 m^2 normal to a line connecting it to a point source of gamma radiation. The source emits photons uniformly in **all** directions. The area and the source are separated by a distance of 2.0 m .

The source emits 5000 gamma photons per second.

How many photons pass through the area every second?

[1 mark]

- A** 500 ☐
- B** 250 ☐
- C** 10 ☒
- D** 2.5 ☐

2 8

X and **Y** are two radioactive nuclides. **X** has a half-life of 3.0 minutes and **Y** has a half-life of 9.0 minutes.

Two freshly prepared samples of **X** and **Y** start decaying at the same time. After 18 minutes the number of radioactive nuclei in both samples is the same. The sample of **Y** initially contained N radioactive nuclei.

What was the initial number of radioactive nuclei in the sample of **X**?

[1 mark]

A $4N$ ☐

B $16N$ ☒

C $32N$ ☐

D $64N$ ☐

2 9

What is the main purpose of a moderator in a thermal nuclear reactor?

[1 mark]

A to shield the surroundings from ionising radiations ☐

B to decrease the number of fission chain reactions ☐

C to decrease neutron speeds ☒

D to prevent the core from overheating ☐

3 0

In the core of a nuclear reactor, the mass of fuel decreases at a rate of $9.0 \times 10^{-6} \text{ kg hour}^{-1}$ due to nuclear reactions.

What is the maximum power output of the reactor?

[1 mark]

A $2.3 \times 10^8 \text{ W}$ ☒

B $1.4 \times 10^{11} \text{ W}$ ☐

C $8.1 \times 10^{11} \text{ W}$ ☐

D $2.9 \times 10^{15} \text{ W}$ ☐

3 1

$^{27}_{12}\text{Mg}$ can decay by beta minus emission to one of two possible excited states of $^{27}_{13}\text{Al}$.

Both excited states decay by the emission of a gamma photon directly to the ground state.

The diagram shows the energy levels and two routes for the beta decay.

One route results in the emission of a gamma photon with a higher frequency than the other photon.

What is the maximum possible kinetic energy for the beta particle emitted in this route?

[1 mark]

A 1.33×10^{-13} J

☐

B 1.63×10^{-13} J

☐

C 2.55×10^{-13} J

☒

D 2.85×10^{-13} J

☐
