AS PHYSICS

Paper 1

Time allowed: 1 hour 30 minutes

Materials

For this paper you must have:

- a pencil and a ruler
- a scientific calculator
- a Data and Formulae Booklet
- a protractor.

Instructions

- Use black ink or black ball-point pen.
- Fill in the boxes at the top of this page.
- Answer **all** questions.
- You must answer the questions in the spaces provided. Do not write outside the box around each page or on blank pages.
- If you need extra space for your answer(s), use the lined pages at the end of this book. Write the question number against your answer(s).
- Do **all** rough work in this book. Cross through any work you do not want to be marked.
- Show **all** your working.

Information

- The marks for questions are shown in brackets.
- The maximum mark for this paper is 70.
- You are expected to use a scientific calculator where appropriate.
- A Data and Formulae Booklet is provided as a loose insert.

Answer **all** questions in the spaces provided.

0 1 . 1 Identify the number of neutrons in a nucleus of polonium-210 ($^{210}_{84}\text{Po}$).

Tick (✓) **one** box.

[1 mark]

84

☐

126

☒

210

☐

294

☐

0 1 . 2 A polonium-210 nucleus is formed when a stationary nucleus of bismuth-210 decays. A beta-minus (β^-) particle is emitted in this decay.

Outline, with reference to β^- decay, why bismuth-210 and polonium-210 have different proton numbers.

[2 marks]

In β^- decay a neutron in the bismuth-210 nucleus decays into a proton,

emitting an electron (β^-) and an electron antineutrino: $n \rightarrow p + e^- + \bar{\nu}_e$.

So the proton number increases by one, from 83 to 84, so polonium-210 has one more proton than bismuth-210.

The kinetic energies of β^- particles emitted from a sample of bismuth-210 are analysed. These β^- particles have a range of kinetic energies.

The total energy released when each nucleus of bismuth-210 decays to a nucleus of polonium-210 is 1.2 MeV.

Figure 1 shows the variation with E_k of the number of β^- particles that have the kinetic energy E_k .

0 1 3

Explain how the data in **Figure 1** support the hypothesis that a third particle is produced during β^- decay.

[2 marks]

Energy is conserved, but most β^- particles have a kinetic energy less than 1.2 MeV, so there is missing energy (the law of conservation of energy appears to be violated).

The missing energy (1.2 MeV minus E_k) must be carried off by a third particle, a (anti)neutrino.

Question 1 continues on the next page

Turn over ►

0 1 4 This third particle is an electron antineutrino.

Explain why an electron antineutrino, rather than an electron neutrino, is produced during β^- decay.

[2 marks]

It must be an antineutrino to conserve lepton number.

The electron has a lepton number of +1 and the electron antineutrino has a lepton number of -1, so the total lepton number is zero, as it was before the decay ($n \rightarrow p + e^- + \bar{\nu}_e$; $0 = 0 + 1 - 1$). A neutrino (+1) would give a total of 2.

0 1 5 A large tank of water is used as part of an electron antineutrino detector. An electron antineutrino $\bar{\nu}_e$ enters the tank and interacts with a proton (p).

Figure 2 represents this interaction.

Figure 2

Identify **X** and **Y**.

[2 marks]

X = W^- boson

Y = neutron (n)

0 1 . 6

The positron produced in the interaction in **Figure 2** slows down and collides with a lepton in a molecule of water.

Describe the process that occurs when the positron collides with this lepton.
In your answer you should identify the lepton in the molecule of water.

[3 marks]

The lepton in the water molecule is an electron.

*The positron and the electron annihilate, and their mass is converted
into energy.*

Two gamma photons are produced, which travel in opposite directions.

0 1 . 7

The range of the electromagnetic interaction is infinite.

Table 1 gives the range of the strong nuclear interaction and the range of the weak nuclear interaction.

Table 1

Interaction	Range / m
strong nuclear	10^{-15}
weak nuclear	10^{-18}

Deduce whether the positron or the electron antineutrino is likely to travel the shorter distance in the tank of water before interacting.

[3 marks]

The positron is likely to travel the shorter distance.

*The positron is charged, so it interacts via the electromagnetic
interaction, but the antineutrino is neutral, so it only interacts via the
weak interaction.*

*The weak interaction has a very short range (10^{-18} m), so the
antineutrino must get very close to a particle to interact, so it travels
further. The electromagnetic interaction has an infinite range, so the
positron interacts with more particles and travels a shorter distance.*

15

Turn over ►

0 2

A student removes the reflective layer from a DVD. She uses the DVD as a transmission diffraction grating.

Figure 3 shows light from a laser pointer incident normally on a small section of this diffraction grating. The grooves on this section act as adjacent slits of the transmission diffraction grating.

A vertical pattern of bright spots (maxima) is observed on a circular screen behind the disc.

Figure 3

0 2 . 1

Light of wavelength λ travels from each illuminated slit, producing maxima on the screen.

State the path difference between light from adjacent slits when this light produces a first-order maximum on the screen.

[1 mark]

One wavelength, λ .

0	2	.	2
---	---	---	---

Explain how light from the diffraction grating forms a maximum on the screen.

[3 marks]

Light from each slit undergoes diffraction (spreads out), so the light from the slits overlaps.

The waves meet and superpose. At a maximum the path difference is a whole number of wavelengths ($n\lambda$), so the waves arrive at the screen in phase (zero phase difference).

So they interfere constructively, producing a bright spot.

Question 2 continues on the next page

Turn over ►

The student has three discs: a Blu-ray disc, a DVD and a CD. She removes the reflective coating from the discs so that they act as transmission diffraction gratings. These diffraction gratings have different slit spacings.

The student also has two laser pointers **A** and **B** that emit different colours of visible light.

Table 2 and **Table 3** show information about the discs and the laser pointers.

Table 2

Disc	Slit spacing / μm
Blu-ray disc	0.32
DVD	0.74
CD	1.60

Table 3

Laser pointer	Wavelength of light emitted / 10^{-7} m
A	4.45
B	6.36

0 2 . 3

Deduce the combination of disc and laser pointer that will produce the **greatest** possible number of interference maxima.

[2 marks]

Laser pointer A with the CD.

The greatest number of maxima is given by $n_{\max} = d/\lambda$ (from $d \sin \theta = n\lambda$ with $\sin \theta \leq 1$), so the smallest wavelength (A, $4.45 \times 10^{-7} \text{ m}$) and the largest slit spacing (CD, $1.60 \mu\text{m}$) give the most maxima.

0 2 . 4

The student uses the CD and laser pointer **B** as shown in **Figure 4**. A diffraction pattern is produced on the screen. Laser pointer **B** and the CD are in fixed positions. The laser beam is horizontal and incident normally on the CD. The height of the screen can be adjusted.

Figure 4

The screen has a diameter of 30 cm and is positioned behind the CD at a fixed horizontal distance of 15 cm.

The student plans to adjust the height of the screen until she observes the greatest number of spots.

The student predicts that, using this arrangement, the greatest number of spots on the screen will be 3.

Determine whether the student's prediction is correct.

[3 marks]

$$n\lambda = d \sin \theta: n = 1: \sin \theta_1 = 6.36 \times 10^{-7} \div 1.60 \times 10^{-6} = 0.398, \theta_1 = 23.4^\circ$$

$$n = 2: \sin \theta_2 = 2 \times 6.36 \times 10^{-7} \div 1.60 \times 10^{-6} = 0.795, \theta_2 = 52.7^\circ$$

($n = 3$ gives $\sin \theta = 1.19 > 1$, so not possible)

$$\text{Screen 30 cm wide at 15 cm subtends } 2 \times \tan^{-1}(15/15) = 2 \times 45^\circ = 90^\circ$$

$$\theta_2 + \theta_1 = 52.7^\circ + 23.4^\circ = 76.1^\circ < 90^\circ, \text{ or using } \tan \theta = r/15:$$

$$r_1 = 15 \tan 23.4^\circ = 6.5 \text{ cm}, r_2 = 19.7 \text{ cm}, 6.5 + 19.7 = 26.2 \text{ cm} < 30 \text{ cm}$$

No, the prediction is wrong: with the screen raised, the 1st order spot

below the centre, the zero order and the 1st and 2nd order spots above

all fit, so 4 bright spots can be seen.

0 3

Figure 5 shows a spacecraft travelling towards a comet. The spacecraft has an array of blocks designed to capture small dust particles from the comet's tail.

Figure 5

To test the blocks before launch, a spherical dust particle **P** is fired at a right angle to the surface of a fixed, stationary block.

P has a mass of 1.1×10^{-9} kg. It has a speed of 5.9×10^3 m s⁻¹ when it hits the surface of the block.

P comes to rest inside the block.

0 3 . 1

Calculate the work done in bringing **P** to rest.

[1 mark]

$$W = \text{loss of KE} = \frac{1}{2}mv^2 = 0.5 \times 1.1 \times 10^{-9} \times (5.9 \times 10^3)^2$$

$$\text{work done} = \underline{0.019} \text{ J}$$

0 3 . 2

P travels a distance of 2.9 cm in a straight line inside the block before coming to rest. The resultant force on **P** varies as it penetrates the block.

Calculate the average force acting on **P** as it is brought to rest.

[2 marks]

$$W = Fs \text{ so } F = W / s$$

$$F = 0.0191 \div 2.9 \times 10^{-2}$$

$$F = 0.66 \text{ N}$$

$$\text{average force} = \underline{0.66} \text{ N}$$

0 3 . 3

The block is rectangular with an area of cross-section of 8.0 cm^2 and a thickness of 3.0 cm .

Figure 6 shows how the density of the block varies with depth up to its maximum thickness.

Figure 6

Calculate the mass of the block.

[4 marks]

$$\text{Volume} = \text{thickness} \times \text{area of cross-section}$$

$$V = 0.030 \times 8.0 \times 10^{-4} = 2.4 \times 10^{-5} \text{ m}^3$$

Density increases linearly from 5 to 50 kg m^{-3} , so

$$\text{average density} = (50 + 5) \div 2 = 27.5 \text{ kg m}^{-3}$$

$$\text{density} = \text{mass} / \text{volume} \quad \text{so} \quad \text{mass} = \rho V$$

$$\text{mass} = 27.5 \times 2.4 \times 10^{-5} = 6.6 \times 10^{-4} \text{ kg}$$

$$\text{mass} = \underline{6.6 \times 10^{-4}} \text{ kg}$$

Question 3 continues on the next page

Turn over ►

0 3 . 4

In another test, a spherical particle **Q** is fired at a right angle to the surface of an identical block.

Q has the same mass as **P** and is travelling at the same speed as **P** when it strikes the surface of the block.

Q is made from a less dense material than **P**.

Compare the distance travelled by **Q** with that travelled by **P** as they are brought to rest.

[3 marks]

Q travels a shorter distance than P.

Q is less dense, so for the same mass (and KE) it has a larger volume and a larger surface area.

So Q displaces more matter per unit distance and has a greater resistive force (at any speed), so a greater deceleration: it does more work (transfers more KE) per unit distance.

0 4

Figure 7 shows an athlete holding a vaulting pole at an angle of 40° to the horizontal.

Figure 7

Forces D and U are exerted on the pole by the athlete's right and left hands respectively.

U is applied at point Y at an angle θ to the vertical.

The magnitude of D is 53 N and is applied at 90° to the pole at X .

The uniform pole is in equilibrium. It has a weight of 31 N.

Figure 8 shows the forces acting on the pole.

Figure 8

0 4 . 1

Determine, using a scale diagram, θ and the magnitude of U .

[4 marks]

 U measured = 7.9 cm, so $U = 79$ N θ measured with protractor = 25° $\theta =$ 25 $^\circ$ magnitude of $U =$ 79 N

Question 4 continues on the next page

Turn over ►

0 4 . 2

The athlete now moves the pole to a horizontal position. The pole is held stationary in this position.

The athlete's right hand applies a force S vertically downwards at X as shown in **Figure 9**. The athlete's left hand applies a force V at Y .

Figure 9

Discuss the differences between the magnitudes and directions of force U in **Figure 7** and force V applied at Y in **Figure 9**.

[3 marks]

V is vertical (upwards), whereas U is at an angle θ to the vertical, so V has no horizontal component. This is because S and the weight are both vertical in Figure 9, so for equilibrium $V = S + 31\text{ N}$.

V is greater in magnitude than U . With the pole horizontal, the weight has a greater moment about Y than in Figure 7, so S must be larger than D to give a greater moment about Y (they act at the same distance from Y), so $V = S + 31$ is larger.

0 5 . 1

Figure 10 shows a ship leaving a harbour at a constant velocity. The ship moves at the same velocity as a person walking on the harbour wall alongside the ship.

Figure 10

The momentum of the ship is approximately $1 \times 10^7 \text{ N s}$.

Estimate the mass of the ship.

[2 marks]

Estimate walking speed of person $\approx 1.5 \text{ m s}^{-1}$

$$p = mv \text{ so } m = p / v$$

$$m = 1 \times 10^7 \div 1.5 = 6.7 \times 10^6 \text{ kg}$$

mass of ship = 7×10^6 kg

Question 5 continues on the next page

Turn over ►

0 5 . 2

Figure 11 shows the direction of the thrust exerted by the ship's propeller as the propeller rotates. The ship's engine makes the propeller rotate. When more water is accelerated, more work is done by the engine.

Figure 11

Explain, using Newton's laws of motion, how the thrust of the propeller on the water enables the ship to maintain a constant momentum.

[4 marks]

The propeller exerts a force (thrust) on the water, accelerating it backwards. A force is needed to change the momentum of the water: by Newton's 2nd law, force = rate of change of momentum.

By Newton's 3rd law, the water exerts an equal force on the propeller (and so on the ship) in the opposite direction, i.e. forwards.

This forward force on the ship is equal to the drag force on the ship, so the resultant force on the ship is zero. By Newton's 1st law the ship keeps moving at a constant velocity, so its momentum stays constant.

0 5 . 3

Figure 12 shows the bottom of the hull with a drag reduction system in operation. Air bubbles are introduced into the water below the hull. This reduces the work done per second against the drag on the hull at any given speed.

However, when the air bubbles reach the propeller they decrease the mass of water being accelerated by the propeller every second. This decreases the thrust produced by the propeller at a given speed of rotation.

Figure 12

The system enables the ship to save fuel while maintaining the same momentum.

Explain why the system delivers this fuel saving.

In your answer, consider the effects of the introduction of the system on

- the thrust
- the drag on the hull.

[3 marks]

With the system on, the work done per second against drag decreases, and the work done per second by the propeller (thrust) also decreases at any rotational speed, but the drag decreases by more than the thrust.

To maintain a constant momentum, the thrust must equal the drag. So the propeller can operate at a lower rotational speed so that the thrust again equals the (smaller) drag. $\text{Power} = Fv$ is lower, so the engine does less work per second and less fuel needs to be burnt.

0 6

A battery has an emf of 5.30 V and negligible internal resistance.

0 6 . 1

State what is meant by an emf of 5.30 V for this battery.

[2 marks]

*5.30 J of energy is transferred from chemical energy to electrical energy
for every coulomb of charge passing through the battery.*

0 6 . 2

Figure 13 shows the battery connected into a circuit.

Figure 13

The ammeter is ideal.

The voltmeter is non-ideal and has a resistance R .

The reading on the voltmeter is 1.05 V when it is connected across the 320 Ω resistor.

Show that the reading on the ammeter is approximately 7 mA.

[2 marks]

$$pd \text{ across } 640 \, \Omega = 5.30 - 1.05 = 4.25 \, V$$

$$V = IR \text{ so } I = V / R$$

$$I = 4.25 \div 640 = 6.64 \times 10^{-3} \, A$$

$$\approx 7 \, mA$$

06.3

Show that the resistance R of the voltmeter is approximately $300\ \Omega$.

[3 marks]

$$\text{Current in } 320\ \Omega: I_1 = V / R = 1.05 \div 320 = 3.28 \times 10^{-3}\ \text{A}$$

$$\text{Total current } I_T = 6.64 \times 10^{-3}\ \text{A} \quad (\text{from 06.2})$$

$$I_T = I_1 + I_2: \text{ current in voltmeter}$$

$$I_2 = 6.64 \times 10^{-3} - 3.28 \times 10^{-3} = 3.36 \times 10^{-3}\ \text{A}$$

$$R = V / I_2 = 1.05 \div 3.36 \times 10^{-3} = 312.6\ \Omega \approx 313\ \Omega$$

$$(\text{Check: } 1/R_{\text{par}} = 1/320 + 1/313, \quad R_{\text{par}} = 158\ \Omega = 1.05 \div 6.64 \times 10^{-3})$$

$$\text{so } R \approx 300\ \Omega$$

06.4

The voltmeter is now connected across the battery terminals.

Calculate the power dissipated in the voltmeter.

[2 marks]

$$P = V^2 / R$$

$$P = 5.30^2 \div 312.6$$

$$P = 0.0899\ \text{W}$$

power = 0.090 W

Question 6 continues on the next page

Turn over ►

0 6 . 5

The voltmeter is now connected across the $640\ \Omega$ resistor as shown in **Figure 14**.

Figure 14

The reading on the voltmeter is 2.10 V .

When the voltmeter was connected across the $320\ \Omega$ resistor, as shown in **Figure 13**, the reading on the voltmeter was 1.05 V .

Explain why the sum of these voltmeter readings does **not** equal the emf of the battery.

[2 marks]

The voltmeter is not ideal, so connecting it in parallel with a resistor reduces the resistance of that part of the circuit, so the total resistance of the circuit decreases (changes).

So the current in the circuit changes as the voltmeter position changes, and the ratio of the voltages across the two resistors changes. Each reading is less than the pd across that resistor without the voltmeter, so the readings do not add up to 5.30 V .

0	7
---	---

Optical fibres are used to carry pulses of light.

0	7	.	1
---	---	---	---

Explain what is meant by modal dispersion in an optical fibre.

[2 marks]

Modal dispersion is the spreading of a pulse (pulse broadening) as it travels along the fibre, because parts of the pulse take different times to travel through the fibre.

This is because light enters the fibre at different angles and so takes different paths through the fibre, some longer than others (e.g. along the axis versus repeated total internal reflections).

Question 7 continues on the next page

Turn over ►

Figure 15 shows a ray of light incident on the central axis of an optical fibre at an angle of incidence of 30° . The optical fibre is straight and horizontal and has a length of 10.0 km.

Figure 15

For light incident on the core at a given angle of incidence, the angle of refraction θ_R varies with the frequency f of the light.

Figure 16 shows how $\sin \theta_R$ varies with f when the angle of incidence is 30° .

Figure 16

The transit time is the time between a pulse of light entering and leaving the optical fibre.

A single pulse of blue light is incident on the air-core boundary at an angle of incidence of 30° .

The transit time of this pulse along the 10 km length of the optical fibre is 5.225×10^{-5} s.

0 7 . 2

Show that the horizontal component of the velocity of the pulse is approximately 1.9×10^8 m s⁻¹.

[1 mark]

$$\text{horizontal speed} = \text{distance} / \text{time}$$

$$= 10.0 \times 10^3 \div 5.225 \times 10^{-5}$$

$$= 1.91 \times 10^8 \text{ m s}^{-1} \quad (\approx 1.9 \times 10^8 \text{ m s}^{-1})$$

0 7 . 3

The frequency of the blue light in the pulse is 720 THz.

Calculate the speed of the blue light in the core of the optical fibre.

[3 marks]

$$\text{From Figure 16 at 720 THz: } \sin \theta_R = 0.3391$$

$$n_1 \sin \theta_1 = n_2 \sin \theta_2: 1.00 \times \sin 30^\circ = n \times 0.3391$$

$$n = 0.500 \div 0.3391 = 1.47$$

$$n = c / c_s \text{ so } c_s = c / n$$

$$c_s = 3.00 \times 10^8 \div 1.474 = 2.03 \times 10^8 \text{ m s}^{-1}$$

$$(\text{Check: } \theta_R = 19.8^\circ, c_s \cos 19.8^\circ = 1.91 \times 10^8 \text{ m s}^{-1})$$

$$\text{speed} = \underline{2.03 \times 10^8} \text{ m s}^{-1}$$

Question 7 continues on the next page

Turn over ►

07.4

Two pulses of monochromatic light are incident normally on the air–core boundary. They then travel along the central axis of the core. One pulse consists of blue light; the other consists of red light.

Explain, with reference to refractive index, why the pulse of red light has a shorter transit time than the pulse of blue light.

[2 marks]

The refractive index of the core for blue light is greater than the refractive index for red light (n increases with frequency, as Figure 16 shows $\sin \theta_R$ decreasing).

Since $n = c / c_s$, the speed of the red light in the core is greater than the speed of the blue light, and both travel the same distance along the axis, so the red pulse has a shorter transit time.

07.5

Another two pulses, identical to the pulses in Question 07.4, are incident on the central axis of the optical fibre and travel along its length. However, the pulse of red light and pulse of blue light are now incident on the air–core boundary at an angle of incidence of 30° .

Suggest **one** reason why the difference in their transit times may **not** be the same as in Question 07.4.

[1 mark]

The red light refracts less, so it now travels a greater distance (more zig-zag path) than the blue light, whereas in 07.4 they travelled the same distance, so the difference in their horizontal velocities is smaller.
