INTERNATIONAL A-LEVEL PHYSICS

Unit 4 Energy and Energy resources

Wednesday 20 January 2021

07:00 GMT

Time allowed: 2 hours

Materials

For this paper you must have:

- a Data and Formulae Booklet as a loose insert
- a ruler with millimetre measurements
- a scientific calculator, which you are expected to use where appropriate
- a protractor.

Instructions

- Use black ink or black ball-point pen.
- Fill in the boxes at the top of this page.
- Answer **all** questions.
- You must answer the questions in the spaces provided. Do not write outside the box around each page or on blank pages.
- All working must be shown.
- If you need extra space for your answer(s), use the lined pages at the end of this book. Write the question number against your answer(s).
- Do all rough work in this book. Cross through any work you do not want to be marked.

Information

- The marks for questions are shown in brackets.
- The maximum mark for this paper is 80.

**DO NOT WRITE ON THIS PAGE
ANSWER IN THE SPACES PROVIDED**

Section A

Answer **all** questions in this section.

0 1

The equation $pV = \frac{1}{3}Nm(c_{\text{rms}})^2$ applies to an ideal gas.

0 1 . 1

The derivation of the equation depends on assumptions made about the gas.

State **two** of those assumptions.**[2 marks]**

1 *The particles have negligible volume compared with the volume of the container (point particles).*

2 *There are no (negligible) forces between the particles except during collisions, and all collisions are elastic.*

0 1 . 2

A sample of an ideal gas has a temperature of 12.5 °C.

The mass of each particle of this gas is 6.6×10^{-26} kg.

Calculate c_{rms} (root mean square speed) for the particles in the gas.
Give your answer to an appropriate number of significant figures.

[4 marks]

$$T = 12.5 + 273 = 285.5 \text{ K}$$

$$\frac{1}{2} m(c_{\text{rms}})^2 = \frac{3}{2} kT \quad \text{so} \quad c_{\text{rms}} = \sqrt{3kT / m}$$

$$c_{\text{rms}} = \sqrt{3 \times 1.38 \times 10^{-23} \times 285.5 / (6.6 \times 10^{-26})}$$

$$c_{\text{rms}} = \sqrt{1.79 \times 10^5} = 423 \text{ m s}^{-1}$$

$$= 420 \text{ m s}^{-1} \text{ (2 sf, as the mass is given to 2 sf)}$$

$$c_{\text{rms}} = \underline{420} \text{ m s}^{-1}$$

Turn over ►

0 2

The mass of a nucleus of californium-252 ($^{252}_{98}\text{Cf}$) is 252.03 u.

0 2 . 1

Calculate, in kg, the mass defect of a nucleus of californium-252.

[3 marks]

$$\text{number of protons} = 98, \text{ number of neutrons} = 252 - 98 = 154$$

$$\text{mass of nucleons} = 98 \times 1.00728 \text{ u} + 154 \times 1.00867 \text{ u}$$

$$= 98.71344 + 155.33518 = 254.04862 \text{ u}$$

$$\text{mass defect} = 254.04862 - 252.03 = 2.01862 \text{ u}$$

$$1 \text{ u} = 1.661 \times 10^{-27} \text{ kg}$$

$$\text{mass defect} = 2.01862 \times 1.661 \times 10^{-27} = 3.35 \times 10^{-27} \text{ kg}$$

$$\text{mass defect} = \underline{3.4 \times 10^{-27}} \text{ kg}$$

0 2 . 2

Spontaneous fission of a californium-252 nucleus produces a xenon-140 ($^{140}_{54}\text{Xe}$) nucleus, a ruthenium-108 ($^{108}_{44}\text{Ru}$) nucleus and four neutrons.

Table 1 gives the mass of each nuclide.

Table 1

Nuclide	Mass / u
$^{252}_{98}\text{Cf}$	252.03
$^{140}_{54}\text{Xe}$	139.89
$^{108}_{44}\text{Ru}$	107.88

Calculate, in MeV, the amount of energy released in this fission.

[3 marks]

$$\text{mass of products} = 139.89 + 107.88 + 4 \times 1.00867 = 251.80468 \text{ u}$$

$$\text{mass difference } \Delta m = 252.03 - 251.80468 = 0.22532 \text{ u}$$

$$1 \text{ u} \equiv 931.5 \text{ MeV}$$

$$\text{energy released} = 0.22532 \times 931.5 = 209.9 \text{ MeV}$$

energy released = 210 MeV

Turn over ►

0 3 . 1

Figure 1 shows the current–voltage characteristic for a solar cell.

Figure 1

Estimate the maximum power available from the solar cell.

[2 marks]

maximum power is at the 'knee' of the curve, where $V \times I$ is largest:

$$V = 0.60 \text{ V}, \quad I = 0.85 \text{ A}$$

$$P = VI = 0.60 \times 0.85 = 0.51 \text{ W}$$

maximum power = 0.51 W

0 3 . 2

A different type of solar cell has an emf of 0.72 V and an internal resistance of 2.2Ω when in use.

An array of solar cells of this type has an emf of 3.6 V and an internal resistance of 5.5Ω .

Deduce the number and arrangement of solar cells used to make this array.

[4 marks]

$$\text{number of cells in series} = 3.6 / 0.72 = 5$$

$$\text{internal resistance of 5 cells in series} = 5 \times 2.2 = 11 \Omega$$

$$\text{two of these rows in parallel: } 1/r = 1/11 + 1/11, \quad r = 11 / 2 = 5.5 \Omega$$

(emf of parallel rows stays 3.6 V)

5 cells in series give 3.6 V but 11Ω , so two parallel sets of 5 cells in series are needed to halve the internal resistance to 5.5Ω .

So the array uses 10 cells: 2 parallel rows, each of 5 cells in series.

6

0 4

A gas has a density of 12 kg m^{-3} when its temperature is 860 K and its pressure is $2.1 \times 10^7 \text{ Pa}$.

0 4 . 1

Show that 60 kg of the gas contains approximately 9×10^{27} particles.

[3 marks]

$$\rho = m / V \quad \text{so} \quad V = m / \rho = 60 / 12 = 5.0 \text{ m}^3$$

$$pV = NkT \quad \text{so} \quad N = pV / kT$$

$$N = 2.1 \times 10^7 \times 5.0 / (1.38 \times 10^{-23} \times 860)$$

$$N = 8.8 \times 10^{27} \approx 9 \times 10^{27} \text{ particles}$$

0 4 . 2

Calculate the molar mass of the gas.

State an appropriate unit for your answer.

[3 marks]

$$\text{number of moles } n = N / N_A = 8.85 \times 10^{27} / (6.02 \times 10^{23})$$

$$n = 1.47 \times 10^4 \text{ mol}$$

$$M = m / n = 60 / (1.47 \times 10^4) = 4.1 \times 10^{-3} \text{ kg mol}^{-1}$$

$$= 4.1 \text{ g mol}^{-1}$$

$$\text{molar mass} = \underline{4.1}$$

$$\text{unit} = \underline{\text{g mol}^{-1}}$$

0 4 . 3

The gas is heated at a rate of 75 MW as it flows through a pipe.
A mass of 60 kg of gas flows through the pipe each second.
The gas enters the pipe at a temperature of 860 K.

Calculate the temperature of the gas as it leaves the pipe.

specific heat capacity of the gas = $4.9 \times 10^3 \text{ J kg}^{-1} \text{ K}^{-1}$

[3 marks]

$$Q/t = (m/t) c \Delta\theta$$

$$\Delta\theta = 75 \times 10^6 / (60 \times 4.9 \times 10^3) = 255 \text{ K}$$

$$T = 860 + 255 = 1115 \text{ K} \approx 1100 \text{ K}$$

temperature of the gas = 1100 K

0 4 . 4

The hot gas now enters a cool turbine, forcing the turbine to rotate.

Discuss how the first law of thermodynamics applies to the gas as it forces the turbine to rotate.

[3 marks]

First law: $\Delta U = Q + W$, where W is work done on the gas and Q is heat transferred to the gas.

The gas does work on the turbine as it forces it to rotate, so W is negative.

The turbine is cool, so heat is transferred from the hot gas to the turbine (initially), so Q is also negative.

Therefore ΔU is negative: the internal energy of the gas decreases, so its temperature falls.

12

Turn over ►

0 5

Figure 2 shows the equipment a student uses to find the moment of inertia of a disc. The student wraps a string of negligible mass several times around the disc. The student attaches a mass hanger to the free end of the string. The hanger is released from rest and falls. The disc rotates with a constant angular acceleration.

Figure 2

0 5 . 1

The disc makes exactly three rotations in a time of 2.2 s.

Show that the angular acceleration α of the disc is approximately 8 rad s^{-2} .

[3 marks]

$$\text{angular displacement } \theta = 3 \times 2\pi = 6\pi = 18.85 \text{ rad}$$

$$\text{starts from rest: } \theta = \omega_0 t + \frac{1}{2} \alpha t^2 = \frac{1}{2} \alpha t^2$$

$$\alpha = 2\theta / t^2 = 2 \times 18.85 / 2.2^2$$

$$\alpha = 7.8 \text{ rad s}^{-2} \approx 8 \text{ rad s}^{-2}$$

The tension in the string exerts a torque on the disc.
The hanger has a mass m . It falls with a linear acceleration A .

0 5 . 2 Show that, in the absence of frictional forces,

$$\text{torque on the disc} = m(g - A)r$$

where r is the radius of the disc.

[2 marks]

for the hanger (Newton's second law): $mg - \text{tension} = mA$

$$\text{so tension} = mg - mA = m(g - A)$$

$$\text{torque on disc} = \text{tension} \times r$$

$$\text{torque} = m(g - A)r$$

0 5 . 3 The linear acceleration A is related to the angular acceleration α by

$$A = \alpha r$$

Determine, using the experimental data, the moment of inertia of the disc.

$$r = 2.0 \text{ cm}$$

$$m = 0.10 \text{ kg}$$

[3 marks]

$$A = \alpha r = 7.8 \times 0.020 = 0.156 \text{ m s}^{-2}$$

$$\text{torque} = m(g - A)r = 0.10 \times (9.81 - 0.156) \times 0.020 = 0.0193 \text{ N m}$$

$$\text{torque} = I\alpha \quad \text{so} \quad I = \text{torque} / \alpha$$

$$I = 0.0193 / 7.8 = 2.5 \times 10^{-3} \text{ kg m}^2$$

$$\text{moment of inertia} = \underline{2.5 \times 10^{-3}} \text{ kg m}^2$$

Question 5 continues on the next page

Turn over ►

0 5 . 4

In practice, frictional forces act on the disc as it rotates.

These frictional forces affect the accuracy of the experimental value for the moment of inertia of the disc.

Discuss why.

[3 marks]

Friction provides a resistive torque that opposes the rotation, so the resultant torque on the disc is less than $m(g - A)r$.

This reduces the angular (and linear) acceleration, so the hanger takes longer to fall and the measured α is smaller.

The calculation assumes all of $m(g - A)r$ accelerates the disc, so $I = \text{torque} / \alpha$ gives an experimental value of I that is larger than the actual moment of inertia.

11

0 6

Figure 3 shows a pumped storage system (PSS). Electricity is generated when water flows through a pipe from the upper reservoir to drive a turbine and a generator.

Figure 3

Question 6 continues on the next page

Turn over ►

The water level in the upper reservoir is initially 140 m above the turbine.
The PSS generates electrical energy for an operating time T .
During this operating time:

- the water level decreases by 20 m
- 30 TJ of gravitational potential energy is transferred
- there is a constant electrical power output of 1.8 GW.

0 6 . 1

Calculate the mass of water that leaves the upper reservoir when the water level decreases by 20 m.

[2 marks]

$$\Delta E_p = mgh, \text{ average height fallen } h = 140 - 10 = 130 \text{ m}$$

$$m = \Delta E_p / gh = 30 \times 10^{12} / (9.81 \times 130)$$

$$m = 2.4 \times 10^{10} \text{ kg}$$

$$\text{mass} = \underline{2.4 \times 10^{10}} \text{ kg}$$

0 6 . 2

The efficiency of the transfer from gravitational potential energy to electrical energy is 82%.

Calculate T in hours.

[3 marks]

$$\text{useful electrical energy} = 0.82 \times 30 \times 10^{12} = 2.46 \times 10^{13} \text{ J}$$

$$\text{energy} = \text{power} \times \text{time} \quad \text{so} \quad T = E / P$$

$$T = 2.46 \times 10^{13} / (1.8 \times 10^9) = 1.37 \times 10^4 \text{ s}$$

$$T = 1.37 \times 10^4 \text{ s} / 3600 = 3.8 \text{ hours}$$

$$T = \underline{3.8} \text{ hours}$$

0 6 . 3

Outline why, during one complete cycle of operation, the efficiency of the PSS is less than 82%.

[2 marks]

In a complete cycle the water must be pumped back up to the upper reservoir, using electrical energy.

The pumping process is also less than 100% efficient (energy is wasted as heat in the motor/pump and by friction in the pipe), so the overall efficiency is lower, about $0.82 \times 0.82 \approx 67\%$.

0 6 . 4

Describe the benefits of using a PSS in an electrical power network.

[3 marks]

It stores energy: at times of low demand, surplus electricity from base-load stations (e.g. nuclear) is used to pump water up to the upper reservoir.

It can then be used to meet sudden surges in demand.

It has a very short start-up time (it can reach full output in seconds to minutes), so it responds quickly to changes in demand.

10

Turn over ►

07

Some proposed fusion reactors will use a fuel of deuterium (${}^2_1\text{H}$) and tritium (${}^3_1\text{H}$).

The fusion reaction produces helium-4 (${}^4_2\text{He}$) and a neutron.

07.1

Explain why this reaction will occur only when the fuel is at a very high temperature.

[2 marks]

The nuclei must come within a few femtometres of each other for the strong nuclear force to act and fusion to occur.

Both nuclei are positive, so they need very high kinetic energy (very high temperature) to overcome the electrostatic repulsion between them.

07.2

The temperature of the fuel in one reactor is 1.2 GK.

Calculate the average kinetic energy of a deuterium nucleus in the fuel. Assume that the fuel behaves as an ideal gas.

[1 mark]

$$E_k = 3/2 kT = 1.5 \times 1.38 \times 10^{-23} \times 1.2 \times 10^9$$

$$E_k = 2.5 \times 10^{-14} \text{ J}$$

average kinetic energy = 2.5×10^{-14} J

07.3

State how the average kinetic energy of a **tritium** nucleus in the fuel compares to your answer to Question 07.2.

[1 mark]

It is the same, $2.5 \times 10^{-14} \text{ J}$ (it depends only on temperature).

07.4

An estimate of the closest approach between a deuterium nucleus and a tritium nucleus can be made using the answers to Question 07.2 and Question 07.3.

Explain how this estimate can be made.

[3 marks]

In a head-on collision, the combined kinetic energy of the two nuclei is available: $2 \times 2.5 \times 10^{-14} = 5.0 \times 10^{-14}$ J.

At closest approach all of this kinetic energy has been transferred to electric potential energy.

Electric potential energy $E_p = Q_1 Q_2 / 4\pi\epsilon_0 r$ (from $V = Q / 4\pi\epsilon_0 r$ and $\Delta W = Q\Delta V$), with $Q_1 = Q_2 = e$, so $r = e^2 / (4\pi\epsilon_0 \times 5.0 \times 10^{-14})$.

Question 7 continues on the next page

Turn over ►

0 7 5

Table 2 shows the binding energy per nucleon for two nuclides involved in the fusion reaction.

The energy released in this fusion reaction is 17.589 MeV.

Table 2

Nuclide	Binding energy per nucleon / MeV
${}^2_1\text{H}$	1.1123
${}^4_2\text{He}$	7.0739

Calculate, in J, the binding energy of the tritium (${}^3_1\text{H}$) nuclide.

[3 marks]

$$\text{binding energy of } {}^2_1\text{H} = 2 \times 1.1123 = 2.2246 \text{ MeV}$$

$$\text{binding energy of } {}^4_2\text{He} = 4 \times 7.0739 = 28.2956 \text{ MeV}$$

$$\text{energy released} = \text{BE}(\text{He}) - \text{BE}(\text{H-2}) - \text{BE}(\text{H-3})$$

$$\text{BE}(\text{H-3}) = 28.2956 - 2.2246 - 17.589 = 8.4820 \text{ MeV}$$

$$= 8.4820 \times 10^6 \times 1.60 \times 10^{-19} = 1.4 \times 10^{-12} \text{ J}$$

$$\text{binding energy} = \underline{1.4 \times 10^{-12}} \text{ J}$$

0 7 . 6

The fusion of a deuterium nucleus and a tritium nucleus initially produces a helium-5 nucleus. This nucleus quickly decays into an unexcited helium-4 nucleus and a neutron.

Show that the kinetic energy of the neutron is four times greater than the kinetic energy of the helium-4 nucleus.

Assume that the helium-5 nucleus is stationary before it decays.

[3 marks]

$$\text{momentum conserved: } 0 = m_{\text{He}}v_{\text{He}} - m_n v_n$$

$$m_{\text{He}} = 4m_n \quad \text{so} \quad 4m_n v_{\text{He}} = m_n v_n, \quad v_n = 4v_{\text{He}}$$

$$E_{k,n} / E_{k,\text{He}} = (1/2 m_n v_n^2) / (1/2 m_{\text{He}} v_{\text{He}}^2)$$

$$= (m_n \times 16v_{\text{He}}^2) / (4m_n \times v_{\text{He}}^2) = 16 / 4 = 4$$

The neutron has 4 times the speed, so 16 times the v^2 , but only 1/4 of the mass, so $E_{k,n} = 16/4 \times E_{k,\text{He}} = 4E_{k,\text{He}}$.

0 7 . 7

Designers of fusion reactors have to consider the risks associated with neutrons which have high kinetic energies.

Suggest **one** of these risks.

[1 mark]

Neutrons damage the reactor structure and make materials radioactive (induced radioactivity).

14

END OF SECTION A

Turn over ►

Section B

Each of the questions in this section is followed by four responses, **A**, **B**, **C** and **D**.

For each question select the best response.

Only **one** answer per question is allowed.

For each question, completely fill in the circle alongside the appropriate answer.

CORRECT METHOD

WRONG METHODS

If you want to change your answer you must cross out your original answer as shown. 

If you wish to return to an answer previously crossed out, ring the answer you now wish to select as shown. 

You may do your working in the blank space around each question but this will not be marked.
Do **not** use additional sheets for this working.

0 8

At absolute zero, an ideal gas will

[1 mark]

A condense to a liquid.

☐

B exert zero pressure.

☒

C have maximum potential energy.

☐

D have zero electrical resistance.

☐

0 9

Two materials **X** and **Y** of equal cross-sectional area are joined together.

The left-hand surface of **X** is at a temperature of $100\text{ }^{\circ}\text{C}$. The right-hand surface of **Y** is at a temperature of $0\text{ }^{\circ}\text{C}$.

The rates of heat transfer through **X** and **Y** are the same.

Insulation prevents heat transfers from the top, bottom and sides of each material so that heat transfer occurs only in the direction shown.

The thermal conductivity of **X** is a quarter of the thermal conductivity of **Y**.

The thickness of **X** is twice the thickness of **Y**.

What is the temperature at the junction between **X** and **Y**?

[1 mark]

- A** $11\text{ }^{\circ}\text{C}$ ☐

2 2

An ideal gas goes through a cycle of changes **XYZX** as shown in the pressure–volume graph.

What is the net work done during the cycle **XYZX**?

[1 mark]

- A** 1.2×10^8 J **on** the gas ☐
- B** 1.2×10^8 J **by** the gas ☒
- C** 1.5×10^8 J **on** the gas ☐
- D** 1.5×10^8 J **by** the gas ☐
