Unit 4 Energy and Energy resources

Tuesday 11 June 2024

07:00 GMT

Time allowed: 2 hours

Materials

For this paper you must have:

- a Data and Formulae Booklet as a loose insert
- a ruler with millimetre measurements
- a scientific calculator, which you are expected to use where appropriate
- a protractor.

Instructions

- Use black ink or black ball-point pen.
- Fill in the boxes at the top of this page.
- Answer **all** questions.
- You must answer the questions in the spaces provided. Do not write outside the box around each page or on blank pages.
- All working must be shown.
- If you need extra space for your answer(s), use the lined pages at the end of this book. Write the question number against your answer(s).
- Do all rough work in this book. Cross through any work you do not want to be marked.

Information

- The marks for questions are shown in brackets.
- The maximum mark for this paper is 80.

Section AAnswer **all** questions in this section.**0 1**

Figure 1 shows part of a small hydroelectric power (HEP) station. Some of the river water enters the extraction pipe. This water flows through a turbine before it re-enters the river.

The flow in the river can vary, depending on the weather.

Figure 1

For this HEP station:

- the water falls a vertical distance of 25 m
- the mean electrical power output is 79 kW
- the efficiency is 86%.

0 1 . 1

Calculate the mean mass of water entering the extraction pipe every second.

[3 marks]

$$\text{input power} = \text{output} / \text{efficiency} = 79 \times 10^3 / 0.86 = 9.19 \times 10^4 \text{ W}$$

$$\text{every second: input power} = (\text{mass per second}) \times g \times h$$

$$\text{mass per second} = 9.19 \times 10^4 / (9.81 \times 25)$$

$$= 375 \text{ kg (each second)}$$

mean mass = 375 kg

- 0 1 . 2** The HEP station has an alternating output of voltage 69 kV rms.

Calculate the peak current output from the HEP station.

[2 marks]

$$P = V_{rms} I_{rms} \text{ so } I_{rms} = 79 \times 10^3 / 69 \times 10^3 = 1.14 \text{ A}$$

$$I_0 = \sqrt{2} \times I_{rms} = \sqrt{2} \times 1.14 = 1.62 \text{ A}$$

peak current = 1.62 A

A second type of HEP station uses a dam and a reservoir to store water.

- 0 1 . 3** Suggest **one** environmental benefit of the station shown in **Figure 1** compared with one that uses a dam and a reservoir.

[1 mark]

It does not flood a large area behind a dam, so it does not destroy large areas of habitat.

- 0 1 . 4** State what is meant by a base-power station.
Go on to discuss whether either type of HEP station can operate as a base-power station.

[3 marks]

A base-power station must provide (a constant) power output all of the time, 24 hours a day.

The river station (Figure 1) depends on the river flow, which varies with the weather, so it cannot give a constant output; it could only be base power if the river flow were reliable enough.

The dam station can release stored water when the normal river flow is not enough, so it could sustain a constant output if the reservoir is big enough, but not if the water level drops too much.

Turn over ►

0 2

Figure 2 shows a filament lamp with a total power output of 60.0 W. The glass wall of the lamp has a uniform thickness of 0.64 mm.

Figure 2

Assume the lamp to be a glass sphere of external diameter 5.60 cm.

The lamp is turned on and reaches thermal equilibrium.

The temperature difference across the glass wall is now 1.2 K.

0 2 . 1

Calculate the percentage of the power output of the lamp that transfers through the glass by conduction.

thermal conductivity of glass = $1.10 \text{ W m}^{-1} \text{ K}^{-1}$

[3 marks]

$$r = 5.60 / 2 = 2.80 \text{ cm} = 2.80 \times 10^{-2} \text{ m}$$

$$A = 4\pi r^2 = 4\pi \times (2.80 \times 10^{-2})^2 = 9.85 \times 10^{-3} \text{ m}^2$$

$$P = kA\Delta\theta / L = 1.10 \times 9.85 \times 10^{-3} \times 1.2 / 0.64 \times 10^{-3}$$

$$P = 20.3 \text{ W}$$

$$\text{percentage} = 20.3 / 60.0 \times 100 = 33.9 \%$$

percentage of power output = 34 %

0 2 . 2

At equilibrium, the mean temperature of the glass wall is 131 °C.

Calculate the energy needed to increase the temperature of the glass from 20 °C to 131 °C.

density of glass = $2.5 \times 10^3 \text{ kg m}^{-3}$
specific heat capacity of glass = $0.84 \text{ kJ kg}^{-1} \text{ K}^{-1}$

[3 marks]

$$\text{inner radius} = 2.80 - 0.064 = 2.736 \text{ cm}$$

$$V = \frac{4}{3} \pi (r_2^3 - r_1^3) = \frac{4}{3} \pi (0.02800^3 - 0.02736^3)$$

$$V = 6.16 \times 10^{-6} \text{ m}^3$$

$$m = \rho V = 2.5 \times 10^3 \times 6.16 \times 10^{-6} = 1.54 \times 10^{-2} \text{ kg}$$

$$Q = mc\Delta\theta = 1.54 \times 10^{-2} \times 840 \times (131 - 20) = 1436 \text{ J}$$

energy = 1440 J

6

Turn over for the next question

Turn over ►

0 3

A deuterium (${}^2_1\text{H}$) nucleus with an initial kinetic energy of $1.6 \times 10^{-14} \text{ J}$ approaches a second deuterium nucleus head-on. The second nucleus is initially stationary.

When the nuclei have reached a minimum separation d , each nucleus has a kinetic energy of $4.0 \times 10^{-15} \text{ J}$.

0 3 . 1

Calculate d .

[3 marks]

loss of kinetic energy = gain in electric potential energy

$$\Delta E_k = 1.6 \times 10^{-14} - 2 \times 4.0 \times 10^{-15} = 8.0 \times 10^{-15} \text{ J}$$

$$E_p = Q^2 / 4\pi\epsilon_0 d: 8.0 \times 10^{-15} = (1.60 \times 10^{-19})^2 / (4\pi \times 8.85 \times 10^{-12} \times d)$$

$$d = 2.56 \times 10^{-38} / (4\pi \times 8.85 \times 10^{-12} \times 8.0 \times 10^{-15}) = 2.9 \times 10^{-14} \text{ m}$$

$$d = \underline{2.9 \times 10^{-14}} \text{ m}$$

0 3 . 2

On another occasion, two deuterium (${}^2_1\text{H}$) nuclei have initial kinetic energies of $1.6 \times 10^{-14} \text{ J}$ each.

On this occasion, their minimum separation is different from the value of d in Question **03.1**.

Suggest, without calculation, how this minimum separation differs from the value of d in Question **03.1**.

[3 marks]

If the nuclei move head-on in opposite directions, the total momentum is zero, so at closest approach both nuclei are momentarily at rest (zero kinetic energy).

All the kinetic energy, $3.2 \times 10^{-14} \text{ J}$, is converted to potential energy: 4 times the $8.0 \times 10^{-15} \text{ J}$ in 03.1.

The distance of closest approach is inversely proportional to the change in kinetic energy, so the minimum separation is smaller, about $d/4$.

03.3

The minimum distances in Question 03.1 and Question 03.2 are both too large for the two nuclei to fuse.

Deuterium nuclei can fuse in a plasma in which the mean kinetic energy of nuclei is $1.6 \times 10^{-14} \text{ J}$.

Suggest why some deuterium nuclei can fuse in this plasma.

[1 mark]

The nuclei in the plasma have a range of kinetic energies, so some have much more than the mean and get close enough to fuse.

03.4

Explain **two** reasons why the kinetic theory of gases can model the behaviour of an ideal gas but cannot model the behaviour of a plasma.

[2 marks]

1 *Kinetic theory assumes no forces between particles except in collisions, but plasma ions are charged so there are large electrostatic forces (potential energy) between them.*

2 *It assumes collision time is negligible compared with time between collisions, but charged ions interact over a large range of distances, so this is not true.*

03.5

An ideal gas has particles with a mean kinetic energy of $1.6 \times 10^{-14} \text{ J}$.

Calculate the absolute temperature of the gas.

[2 marks]

$$\text{mean } E_k = \frac{3}{2} kT$$

$$T = 2E_k / 3k = 2 \times 1.6 \times 10^{-14} / (3 \times 1.38 \times 10^{-23})$$

$$T = 7.7 \times 10^8 \text{ K}$$

absolute temperature = 7.7×10^8 K

11

Turn over ►

0 4

The solar fusion cycle has three stages.
The equation for the reaction in the third stage of the cycle is:

Table 1 shows the mass of each particle involved.

Table 1

Particle	Mass / u
${}^3_2\text{He}$	3.016029
${}^4_2\text{He}$	4.002603
${}^1_1\text{p}$	1.007823

0 4 . 1

Show that the energy equivalent of a mass of 1 u is approximately 930 MeV.

$$1 \text{ u} = 1.661 \times 10^{-27} \text{ kg}$$

[2 marks]

$$E = mc^2 = 1.661 \times 10^{-27} \times (3.00 \times 10^8)^2 = 1.495 \times 10^{-10} \text{ J}$$

$$1 \text{ MeV} = 1.60 \times 10^{-13} \text{ J}$$

$$E = 1.495 \times 10^{-10} / 1.60 \times 10^{-13} = 934 \text{ MeV} \approx 930 \text{ MeV}$$

0 4 . 2

Calculate, in MeV, the energy released in one reaction in the third stage of the solar fusion cycle.

[2 marks]

$$\text{mass defect} = 2 \times 3.016029 - 4.002603 - 2 \times 1.007823 = 0.013809 \text{ u}$$

$$\text{energy} = 0.013809 \times 934 = 12.9 \text{ MeV}$$

energy = 12.9 MeV

The equation for a reaction in the second stage of the solar fusion cycle is:

Table 2 shows the binding energy of each particle involved.

Table 2

Particle	Binding energy / pJ
${}^2_1\text{H}$	0.35593
${}^1_1\text{p}$	0
${}^3_2\text{He}$	1.23489
γ	0

0 4 . 3

Explain how the second stage contributes approximately 1.8×10^{-12} J of the energy released in one complete cycle.

Support your explanation with a calculation.

[2 marks]

$$\text{increase in binding energy} = 1.23489 - 0.35593 = 0.87896 \text{ pJ}$$

$$\text{two second-stage reactions per cycle: } 2 \times 0.87896 = 1.758 \text{ pJ}$$

A third-stage reaction needs two helium-3 nuclei, so two second-stage

reactions occur per cycle: total 1.758 pJ $\approx 1.8 \times 10^{-12}$ J.

0 4 . 4

Write the equation for the reaction in the first stage of the solar fusion cycle.

[2 marks]

Question 4 continues on the next page

Turn over ►

0 4 . 5 It is estimated that the Sun contains 2×10^{30} kg of hydrogen (${}^1_1\text{H}$) and emits energy at the rate of 4×10^{26} W.

Each solar fusion cycle produces 4.5×10^{-12} J of energy.

Estimate, in years, the maximum length of time for which the Sun can continue to emit energy at its current rate using only the solar fusion cycle.

$$\text{mass of 1.0 mol of } {}^1_1\text{H} = 1.0 \times 10^{-3} \text{ kg}$$

[4 marks]

$$\text{moles of H} = 2 \times 10^{30} / 1.0 \times 10^{-3} = 2 \times 10^{33} \text{ mol}$$

$$\text{nuclei} = 2 \times 10^{33} \times 6.02 \times 10^{23} = 1.2 \times 10^{57}$$

$$4 \text{ hydrogen nuclei per cycle: cycles} = 1.2 \times 10^{57} / 4 = 3.0 \times 10^{56}$$

$$\text{energy} = 3.0 \times 10^{56} \times 4.5 \times 10^{-12} = 1.35 \times 10^{45} \text{ J}$$

$$\text{time} = 1.35 \times 10^{45} / 4 \times 10^{26} = 3.4 \times 10^{18} \text{ s}$$

$$= 3.4 \times 10^{18} / (3.15 \times 10^7) = 1.07 \times 10^{11} \text{ years}$$

$$\text{time} = \underline{1.1 \times 10^{11}} \text{ years}$$

0 4 . 6 The fusion of two helium nuclei in the core of a star leads to the formation of heavier elements.

Explain why helium fusion requires the plasma temperature to be greater than the temperature needed for hydrogen fusion.

[2 marks]

Helium nuclei have a greater charge (+2e) than hydrogen nuclei (+e),

so the electrostatic repulsion between them is greater and they need

more energy to get close enough to fuse.

So the nuclei need more kinetic energy, which requires a higher plasma temperature.

0 5

A wind turbine has a rotor with a diameter of 135 m.

0 5 . 1Calculate, in MW, the maximum power available from the air to the turbine when the wind speed is 11.4 m s^{-1} .density of air = 1.2 kg m^{-3} **[2 marks]**

$$P = \frac{1}{2} \rho A v^3 = \frac{1}{2} \times 1.2 \times \pi \times (135/2)^2 \times 11.4^3$$

$$P = 1.27 \times 10^7 \text{ W} = 12.7 \text{ MW}$$

maximum power = 12.7 MW**0 5 . 2**State **two** reasons why the total kinetic energy of the wind passing through the turbine is **not** available to the turbine.**[2 marks]**

1 Not all the moving air interacts with the blades: some passes through the gaps between them.

2 The air must still have some speed (kinetic energy) to leave the rear of the turbine, so 100% cannot be transferred (Betz limit, 59%).

The rotor accelerates from rest to its maximum angular speed of 1.41 rad s^{-1} .**0 5 . 3**

Calculate, in revolutions per minute, the maximum frequency of rotation of the rotor.

[1 mark]

$$f = \omega / 2\pi = 1.41 / 2\pi = 0.224 \text{ rev s}^{-1} \times 60 = 13.5 \text{ rev min}^{-1}$$

frequency = 13.5 revolutions per minute**Turn over ►**

The rotor is connected to an electric generator.
The wind exerts a constant torque on the rotor.

Two types of resistive torque are exerted on the rotor:

- a constant frictional resistive torque of $4.0 \times 10^5 \text{ N m}$
- a varying resistive torque exerted by the generator.

The total resistive torque is T_R .

Figure 3 shows the variation of T_R with time t while the rotor is accelerating. The rotor achieves its maximum angular speed of 1.41 rad s^{-1} at $t = 55 \text{ s}$.

Figure 3

0 5 . 4

Calculate, in MJ, the energy that the wind transfers to the turbine between $t = 55 \text{ s}$ and $t = 60 \text{ s}$.

Use data from **Figure 3**.

[2 marks]

at constant ω , wind torque = $T_R = 4.0 \times 10^6 \text{ N m}$ (Figure 3)

$$P = T\omega = 4.0 \times 10^6 \times 1.41 = 5.64 \times 10^6 \text{ W}$$

$$E = Pt = 5.64 \times 10^6 \times 5 = 2.82 \times 10^7 \text{ J} = 28 \text{ MJ}$$

energy = 28 MJ

The moment of inertia of the rotor is $7.1 \times 10^7 \text{ kg m}^2$.

0 5 . 5

Calculate the initial angular acceleration of the rotor.

[2 marks]

$$\text{wind torque} = 4.0 \times 10^6 \text{ N m}; \text{ initial } T_R = 0.4 \times 10^6 \text{ N m}$$

$$\text{resultant torque} = 4.0 \times 10^6 - 0.4 \times 10^6 = 3.6 \times 10^6 \text{ N m}$$

$$\alpha = T / I = 3.6 \times 10^6 / 7.1 \times 10^7 = 0.051 \text{ rad s}^{-2}$$

$$\text{angular acceleration} = \underline{0.051} \text{ rad s}^{-2}$$

0 5 . 6

Calculate the maximum rotational kinetic energy of the rotor.

[2 marks]

$$E_k = 1/2 I \omega^2 = 1/2 \times 7.1 \times 10^7 \times 1.41^2$$

$$E_k = 7.1 \times 10^7 \text{ J}$$

$$\text{maximum kinetic energy} = \underline{7.1 \times 10^7} \text{ J}$$

0 5 . 7

Explain why the angular acceleration of the rotor varies between $t = 0$ and $t = 55 \text{ s}$.

[3 marks]

As the rotor speeds up, the generator's power output increases, so the resistive torque from the generator increases with time (Figure 3).

The wind torque is constant, so the resultant (net) torque decreases; since $T = I\alpha$, the angular acceleration decreases with time.

From $t = 50 \text{ s}$ to 55 s the resistive torque is equal and opposite to the torque from the wind, so the net torque and the angular acceleration are zero.

0 6

Figure 4 shows a pump connected to a bicycle tyre through a connecting tube and a pressure-operated valve.

Figure 4

Initially, the piston is at the top of the cylinder as shown in **Figure 4**. The cylinder contains $2.5 \times 10^{-4} \text{ m}^3$ of air at a pressure of $1.0 \times 10^5 \text{ Pa}$ and a temperature of 17°C . The initial pressure of the air in the tyre is $4.5 \times 10^5 \text{ Pa}$.

When the pump is operated for the first time, the piston is pushed down quickly. All the air remains in the cylinder until the cylinder pressure is $4.5 \times 10^5 \text{ Pa}$. The valve opens when the cylinder pressure and the tyre pressure are equal. All the air in the cylinder then enters the tyre.

Figure 5 shows the variation of pressure with volume for the air in the cylinder.

Figure 5

0 6 . 1

Determine the work done in compressing the air in the cylinder to a pressure of 4.5×10^5 Pa.

[3 marks]

work done = area under the curve (shaded on Figure 5)

between $V = 0.85 \times 10^{-4} \text{ m}^3$ and $V = 2.5 \times 10^{-4} \text{ m}^3$

one 5×5 square = $0.25 \times 10^{-4} \times 0.5 \times 10^5 = 1.25 \text{ J}$

number of 5×5 squares ≈ 27

work done = $27 \times 1.25 = 33.8 \text{ J}$

work done = 34 J

0 6 . 2

Calculate, in K, the temperature of the air in the cylinder when the pressure has increased to 4.5×10^5 Pa.

[2 marks]

from Figure 5: $V_2 = 0.85 \times 10^{-4} \text{ m}^3$ at $4.5 \times 10^5 \text{ Pa}$

$p_1 V_1 / T_1 = p_2 V_2 / T_2$, $T_1 = 17 + 273 = 290 \text{ K}$

$T_2 = 290 \times (4.5 \times 10^5 \times 0.85 \times 10^{-4}) / (1.0 \times 10^5 \times 2.5 \times 10^{-4})$

$T_2 = 444 \text{ K}$

temperature = 444 K

Question 6 continues on the next page

Turn over ►

0 6 . 3

The tyre needs an additional 0.27 mol of air to be inflated to its correct pressure. The volumes of the connecting tube and the valve are negligible.

Calculate the number of times the pump has to be operated to inflate the tyre.

[3 marks]

$$\text{moles per stroke: } n = pV / RT = 1.0 \times 10^5 \times 2.5 \times 10^{-4} / (8.31 \times 290)$$

$$n = 1.04 \times 10^{-2} \text{ mol}$$

$$\text{number} = 0.27 / 1.04 \times 10^{-2} = 26$$

number = 26

0 6 . 4

Explain, with reference to the first law of thermodynamics, why the temperature of the air in the cylinder increases when the piston is pushed down quickly.

[3 marks]

First law: $\Delta U = Q + W$. Pushing the piston down does work on the gas
(W positive).

The compression is quick, so there is no time for heat transfer to the
surroundings: $Q \approx 0$.

So $\Delta U = W$, the internal energy of the air increases. Internal energy is
the kinetic energy of the molecules, so their mean kinetic energy, and
hence the temperature, increases.

Neutron absorption cross-section σ is measured in cm^2 . Nuclei with a large value of σ are more likely to absorb neutrons.

The table gives nucleon numbers and approximate values of σ for four isotopes.

Which isotope would be most suitable as a moderator in a thermal fission reactor?

[1 mark]

	Nucleon number	σ / cm^2	
A	6	1000	☐
B	7	0.0005	☒
C	181	0.0005	☐
D	177	1000	☐

Used fuel rods from a nuclear reactor are stored in water for a long time. The water contains dissolved boron.

Possible reasons for this type of storage are:

1. to prevent overheating due to radioactive decay of nuclei in the used fuel
2. to shield against radiation from radioactive materials in the used fuel
3. to prevent the possibility of a chain reaction occurring in the remaining uranium in the used fuel.

Which of these reasons are correct?

[1 mark]

- A** 1 and 2 only ☐
- B** 1 and 3 only ☐
- C** 2 and 3 only ☐
- D** 1 and 2 and 3 ☒

1 8

P, **Q** and **R** are objects with the same mass m and the same length L .

P and **R** each consist of a light rod with a point mass of mass $\frac{m}{2}$ at each end.

Q is a uniform rod of mass m . **Q** has a moment of inertia of $\frac{1}{3}mL^2$.

X-X' is the axis of rotation for each object.

Which shows the objects in order of increasing moment of inertia?

[1 mark]

- | | | |
|----------|----------------|----------------------------------|
| A | P, Q, R | ☒ |
| B | P, R, Q | ☐ |
| C | R, P, Q | ☐ |
| D | R, Q, P | ☐ |

A wheel has an initial angular velocity of 10 rad s^{-1} .

The wheel experiences an angular acceleration of -2.0 rad s^{-2} until its angular velocity is -20 rad s^{-1} .

How many revolutions does the wheel make during this change of angular velocity?

[1 mark]**A** 12☐**B** 20☒**C** 75☐**D** 125☐**2 0**

A remote island has renewable sources that generate between 2300 kW and 2900 kW of electrical power.

The island needs a continuous power supply of 2500 kW.

The island also has a pumped storage system that stores an energy of 60 MW h.

The output of the renewable resources falls to its minimum value and remains at this minimum value.

The renewable sources together with the pumped storage system can only supply the island's needs for a time t .

What is t ?

[1 mark]**A** 300 h☒**B** 150 h☐**C** 30 h☐**D** 15 h☐

2 1

A student measures how light intensity I varies with distance d from a filament lamp. The axes show the student's plot of $\frac{1}{\sqrt{I}}$ against d .

The points are not all on a straight line through the origin.

What could be a reason for this?

[1 mark]

- A** The lamp is not a point source of monochromatic light.
- B** A systematic error has occurred in the measurement of d .
- C** An additional light source was present for part of the time.
- D** White light does not obey the inverse-square law.
