Unit 2 Electricity, waves and particles

Tuesday 14 January 2025

07:00 GMT

Time allowed: 2 hours

Materials

For this paper you must have:

- a Data and Formulae Booklet as a loose insert
- a ruler with millimetre measurements
- a scientific calculator, which you are expected to use where appropriate
- a protractor.

Instructions

- Use black ink or black ball-point pen.
- Fill in the boxes at the top of this page.
- Answer **all** questions.
- You must answer the questions in the spaces provided. Do not write outside the box around each question or on blank pages.
- All working must be shown.
- If you need extra space for your answer(s), use the lined pages at the end of this book. Write the question number against your answer(s).
- Do all rough work in this book. Cross through any work you do not want to be marked.

Information

- The marks for questions are shown in brackets.
- The maximum mark for this paper is 80.

Section AAnswer **all** questions in this section.**0 1**A particle travels at a speed of $3.6 \times 10^6 \text{ m s}^{-1}$.

The de Broglie wavelength of the particle is 0.98 pm.

Calculate the mass of the particle.

[2 marks]

$$\lambda = h / mv, \text{ so } m = h / \lambda v$$

$$m = 6.63 \times 10^{-34} / (0.98 \times 10^{-12} \times 3.6 \times 10^6)$$

mass of particle = 1.9×10^{-28} kg**2**

0 2

A cell provides an electric current for 3.0 hours.
Figure 1 shows the variation of the current with time.

Figure 1

Determine, in C, the charge transferred by the cell in this time period of 3.0 hours.

[3 marks]

charge = area under the current-time graph

$$\text{area} = (1.0 \times 1.2) + \frac{1}{2}(1.0 + 0.08) \times 1.8 = 2.172 \text{ A h}$$

$$Q = 2.172 \times 3600 = 7819 \text{ C}$$

charge transferred = 7.8×10^3 C

3

Turn over for the next question

Turn over ►

0 3

Figure 2 shows an experimental arrangement to investigate microwaves.

Figure 2

0 3 . 1

The transmitter produces microwaves of frequency 1.1×10^{10} Hz.

Calculate the wavelength of the microwaves.

[1 mark]

$$\lambda = c / f = 3.00 \times 10^8 / 1.1 \times 10^{10}$$

wavelength = 0.027 m

0 3 . 2

A metal grille is placed between the microwave transmitter and the detector as shown in **Figure 3**.

As the grille is placed in position, the microammeter reading decreases to zero.

Figure 3

The grille is then rotated in the vertical plane by 90° as shown in **Figure 4**.

As the grille is rotated, the microammeter reading increases to a maximum.

Figure 4

The grille is rotated by a further 90° and the microammeter reading again decreases to zero.

State and explain how these observations provide evidence about the nature of microwaves.

[3 marks]

The grille acts as a polariser (polarising filter).

In Figure 3 the microwaves are blocked by the grille; in Figure 4

(rotated 90°) they pass through to the detector, so the microwaves are plane polarised.

Only transverse waves can be polarised, so microwaves are transverse.

0 4

Figure 5 shows how the resistivity of platinum metal varies linearly with temperature over the range shown.

Figure 5

0 4 . 1

A length of platinum wire at a temperature of 0.0°C has a resistance of 99Ω . The diameter of the wire is $1.8 \times 10^{-5} \text{ m}$.

Determine the length of the wire.

[3 marks]

$$\text{from Figure 5, at } 0.0^\circ\text{C: } \rho = 0.97 \times 10^{-7} \Omega \text{ m}$$

$$A = \pi d^2 / 4 = \pi (1.8 \times 10^{-5})^2 / 4 = 2.545 \times 10^{-10} \text{ m}^2$$

$$\rho = RA / l, \text{ so } l = RA / \rho$$

$$l = 99 \times 2.545 \times 10^{-10} / 0.97 \times 10^{-7}$$

length of wire = 0.26 m

0 4 . 2

The linear variation of resistivity with temperature shown in **Figure 5** continues up to 200 °C.

Determine the resistivity of platinum when it is at a temperature of 190 °C.

[2 marks]

$$\text{gradient} = (1.34 - 0.97) \times 10^{-7} / 90 = 4.1 \times 10^{-10} \Omega \text{ m } ^\circ\text{C}^{-1}$$

$$\rho = \rho_0 + \text{gradient} \times \theta$$

$$\rho = 0.97 \times 10^{-7} + 4.1 \times 10^{-10} \times 190 = 1.75 \times 10^{-7} \Omega \text{ m}$$

resistivity = 1.8×10^{-7} $\Omega \text{ m}$

5

Turn over for the next question

Turn over ►

0 5

Figure 6 shows a battery connected to a fixed resistor **R** of resistance $220\ \Omega$ and a variable resistor **R_V**. The battery has an emf of $12.0\ \text{V}$ and negligible internal resistance.

Figure 6

0 5 . 1

When the resistance of **R_V** is varied between zero and its maximum, the range of voltmeter readings is $3.0\ \text{V}$ to $12.0\ \text{V}$.

Deduce the maximum resistance of **R_V**.

[2 marks]

at maximum R_V : pd across $R = 3.0\ \text{V}$, pd across $R_V = 12.0 - 3.0 = 9.0\ \text{V}$

ratio of pds $3 : 9$, so ratio of resistances $R : R_V = 1 : 3$

$$R_V = 3 \times 220$$

maximum resistance = 660 Ω

0 5 . 2

The battery develops a significant internal resistance.

Explain why a voltmeter reading of $12.0\ \text{V}$ is no longer possible.

[2 marks]

There will now be a pd (lost volts) across the internal resistance

whenever a current flows.

The emf is now shared between the internal resistance and the $220\ \Omega$

resistor (terminal pd = emf - lost volts), so the pd across R is always

less than $12.0\ \text{V}$.

0 6

Figure 7 shows a 0.200 kg mass suspended from a spring. The top of the spring is fixed in place.

Figure 7

0 6 . 1

The mass is displaced vertically downwards and released. The mass–spring system oscillates with a frequency of 1.8 Hz.

Determine the spring constant of the spring.

[2 marks]

$$T = 1 / f = 1 / 1.8 = 0.556 \text{ s}$$

$$T = 2\pi\sqrt{m / k}, \text{ so } k = 4\pi^2 m / T^2$$

$$k = 4\pi^2 \times 0.200 / 0.556^2$$

spring constant = 26 N m⁻¹

Question 6 continues on the next page

Turn over ►

Figure 8 shows the spring suspended from a vibration generator. The vibration generator is powered by a signal generator.

Figure 8

0 6 . 2

The frequency of the signal generator is increased slowly from zero. The amplitude of oscillation of the mass increases and then decreases. The amplitude has a maximum value at a frequency of 1.8 Hz.

Explain why the amplitude varies in this way.

[2 marks]

At 1.8 Hz resonance occurs, so the amplitude is a maximum.

This is because the driving (forcing) frequency of the vibration generator is then equal to the natural (resonant) frequency of the mass-spring system, so energy is transferred to the system most efficiently. Above or below 1.8 Hz the driving frequency is different from the natural frequency, so the amplitude is smaller.

0 6 . 3

The experiment is repeated with the mass and spring suspended in a cylinder of water as shown in **Figure 9**.

Figure 9

The frequency is again increased slowly from zero.

Compare the behaviour of the oscillating systems in **Figure 8** and **Figure 9**.

[2 marks]

With the water (Figure 9) the system is more heavily damped, so the amplitude of the oscillations is smaller at all frequencies and the maximum amplitude at resonance is smaller.

The maximum amplitude (resonance) still occurs at about 1.8 Hz, the natural frequency, and the resonance peak is flatter (broader) because more energy is dissipated to the water.

6

Turn over ►

07

Monochromatic light from a laser passes through the centre of a narrow single slit. The light forms a pattern on a screen.

07.1

Describe the appearance of the pattern.

You may support your answer with a labelled diagram.

[2 marks]

A bright central maximum with dimmer secondary maxima on either side, separated by dark minima.

The central maximum is much brighter and twice as wide as each secondary maximum.

07.2

The width of the slit is decreased and a new pattern is observed on the screen.

Describe how this new pattern is different from the pattern in Question 07.1.

[2 marks]

The pattern becomes broader: the central maximum (and each maximum) is wider and the maxima are further apart.

The brightness (intensity) of the maxima decreases.

07.3

The single slit is replaced with a diffraction grating that has 400 lines per mm.
The wavelength of the laser light is 530 nm.
A diffraction pattern is produced.

Calculate the maximum order of this diffraction pattern.

[2 marks]

$$d = 1 / (400 \times 10^3) = 2.5 \times 10^{-6} \text{ m}$$

$$d \sin \theta = n\lambda, \text{ with maximum } \sin \theta = 1: n = d / \lambda$$

$$n = 2.5 \times 10^{-6} / 530 \times 10^{-9} = 4.72$$

n must be a whole number, so round down

maximum order = 4

6

Turn over for the next question

Turn over ►

0 8

Figure 10 shows two small loudspeakers **A** and **B** on stands. **A** and **B** act as point sources of sound waves.

Coherent waves of the same amplitude are emitted from **A** and **B**.

Figure 10

**0 8 . 1**

State what is meant by coherent waves.

[2 marks]

*Coherent waves have the same frequency (and wavelength),
and a constant phase difference (constant phase relationship) between
them.*

A sound meter gives a maximum reading when placed at the centre of the line **AB**. When the meter is moved 5.0 cm towards **B** along the line **AB**, the meter reading decreases to a minimum.

- 0 8 . 2** Explain why the meter gives a minimum reading at this new position.

[3 marks]

Moving 5.0 cm towards B makes the path from A 5.0 cm longer and the path from B 5.0 cm shorter, so the path difference is 10 cm, which is $\lambda / 2$ (wavelength = 20 cm).

The waves from the two loudspeakers therefore arrive in antiphase (180° or π rad out of phase).

They superpose and destructive interference occurs, giving a minimum.

As the meter is moved further towards **B** another maximum is detected, followed by a regular pattern of minima and maxima.

- 0 8 . 3** State the distance between two adjacent minima.
Go on to explain your answer.

[2 marks]

*the path difference changes by $2 \times$ the distance moved;
adjacent minima differ in path difference by one wavelength (20 cm),
so the meter moves $\lambda / 2 = 10$ cm between minima*

distance = 0.10 m

Minimum to minimum spacing is half a wavelength, as for nodes in a stationary wave.

- 0 8 . 4** As the meter gets closer to **B**, the amplitude of the minima increases.
Suggest why.

[2 marks]

Closer to B, the amplitude of the wave from B is greater than that of the wave from A (amplitude falls with distance).

Two unequal amplitudes cannot cancel completely, so the resultant amplitude at a minimum is larger.

Turn over ►

0 9

This question is about different methods of producing white light.

0 9 . 1

A fluorescent tube produces white light from ultraviolet (UV) light.

Explain how UV light is produced in a fluorescent tube.

[3 marks]

Electrons are accelerated through the tube (by the pd) and collide with mercury atoms in the vapour, transferring energy to the atoms.

The collision excites the mercury atom: an electron in the atom is moved up to a higher energy level (or the atom is ionised).

When the electron falls back to a lower energy level the atom de-excites and emits a photon of UV light, of energy equal to the difference between the energy levels.

A type of light-emitting diode (LED) emits UV photons.
White light can be produced from these photons by fluorescence.

0 9 . 2

This LED emits UV radiation at a power of 42 mW.
The radiation consists of photons with a frequency of 7.6×10^{14} Hz.

Calculate the number of UV photons emitted each second from the LED.

[3 marks]

$$E = hf = 6.63 \times 10^{-34} \times 7.6 \times 10^{14} = 5.04 \times 10^{-19} \text{ J}$$

number per second = power / energy per photon

$$N = 42 \times 10^{-3} / 5.04 \times 10^{-19}$$

number of photons emitted each second = 8.3×10^{16}

Figure 11 shows part of the I – V characteristic graph for the LED.

Figure 11

0 9 . 3 The pd across the LED is 3.4 V when it emits UV radiation at a power of 42 mW.

Determine the efficiency of the production of UV radiation in the LED.

[2 marks]

from Figure 11, at 3.4 V: $I = 19 \text{ mA}$

input power $P = IV = 3.4 \times 19 \times 10^{-3} = 64.6 \text{ mW}$

efficiency = useful output / input = $42 / 64.6$

efficiency = 0.65

Question 9 continues on the next page

Turn over ►

0 9 . 4 A different source of white light uses a red LED, a green LED and a blue LED.

Figure 12 shows the I – V characteristic graph for each LED.

Figure 12

Figure 13 shows the LEDs connected in series to a $27\ \Omega$ resistor and a battery of negligible internal resistance.

Figure 13

The current in the circuit is 43 mA.

Determine the emf of the battery.

[3 marks]

pd across $27\ \Omega$ resistor: $V = IR = 43 \times 10^{-3} \times 27 = 1.16\ \text{V}$

from Figure 12 at 43 mA: $V_{\text{red}} = 2.05\ \text{V}$, $V_{\text{green}} = 2.70\ \text{V}$,

$V_{\text{blue}} = 3.05\ \text{V}$

emf = sum of pds in series = $1.16 + 2.05 + 2.70 + 3.05 = 8.96\ \text{V}$

emf = 9.0 V

11

END OF SECTION A

Turn over ►

Section B

Answer **all** questions in this section.

1	0
---	---

Figure 14 shows the seed pod of a tree. The pod consists of two seeds and two wings. When the pod falls, the wings spin to produce an upward force so that the pod travels vertically downwards at a terminal speed.

Figure 14

Figure 15 shows how two students **A** and **B** investigate how one pod falls.

Figure 15

Student **A** marks a horizontal line on the wall at a height of 1.63 m. The line is at the height of student **B**'s eyes when he stands facing the wall.

Student **A** releases the pod from a point higher than the line.
Student **B** measures the time t for the pod to travel at terminal speed between the line on the wall and the floor.

The students make five valid measurements of t .

Table 1 shows four of the measurements and the mean value t_{mean} of all five measurements.

Table 1

t / s					
t_1	t_2	t_3	t_4	t_5	t_{mean}
0.84	0.75	0.85	0.94	0.77	0.83

1 0 . 1 Determine t_3 .

[1 mark]

$$\text{sum of five values} = 5 \times 0.83 = 4.15 \text{ s}$$

$$t_3 = 4.15 - (0.84 + 0.75 + 0.94 + 0.77) = 4.15 - 3.30$$

$$t_3 = \underline{0.85} \text{ s}$$

1 0 . 2 Calculate the percentage uncertainty in t_{mean} .

[2 marks]

$$\text{uncertainty} = \text{half the range} = (0.94 - 0.75) / 2 = 0.095 \text{ s}$$

$$\% \text{ uncertainty} = 0.095 / 0.83 \times 100 = 11.4 \%$$

$$\text{percentage uncertainty} = \underline{11 \%}$$

1 0 . 3 Determine the absolute uncertainty in the mean terminal speed of the pod. Assume that the uncertainty in the height is negligible.

[2 marks]

$$v = 1.63 / 0.83 = 1.96 \text{ m s}^{-1}$$

$$\text{uncertainty} = 11 \% \text{ of } 1.96 = 0.11 \times 1.96$$

$$\text{absolute uncertainty} = \underline{0.22} \text{ m s}^{-1}$$

Question 10 continues on the next page

Turn over ►

1 0 . 4

The investigation is now repeated with student **B** dropping the pod and student **A** measuring the time.
Student **A** is taller than student **B**.

Suggest how the results are likely to be affected by this change.

[2 marks]

The line is below student A's eyes, so there is a parallax error: A sees the pod in line with the mark before it actually reaches the line, so the measured time is larger.

The larger measured time gives a smaller calculated mean terminal speed for the same height of 1.63 m (unless A crouches so his eyes are level with the line).

7

Turn over for the next question

*Do not write
outside the
box*

**DO NOT WRITE ON THIS PAGE
ANSWER IN THE SPACES PROVIDED**

Turn over ►

1 1

Figure 16 shows apparatus used to determine the refractive index of a material.

The material is placed between two internal faces of a glass block. The angle between the two internal faces is 90° . The angle between the vertical face and the angled face of the block is 45° .

A horizontal ray of monochromatic light travelling in air is incident at 90° to the left face of the block.

The refractive index of the glass is 1.52

1 1 . 1

Calculate the change in the speed of light as it passes from air to the glass.

[2 marks]

$$\text{speed in glass} = c / n = 3.00 \times 10^8 / 1.52 = 1.97 \times 10^8 \text{ m s}^{-1}$$

$$\text{change} = 3.00 \times 10^8 - 1.97 \times 10^8$$

$$\text{change in speed of light} = 1.03 \times 10^8 \text{ m s}^{-1}$$

1 1 . 2

The light deviates by 16° from the horizontal as it passes from the glass to the material, as shown in **Figure 16**.

Calculate the refractive index of the material.

[3 marks]

$$\text{angle of incidence in glass} = 45^\circ$$

$$\text{angle of refraction in material} = 45^\circ + 16^\circ = 61^\circ$$

$$n_1 \sin \theta_1 = n_2 \sin \theta_2: 1.52 \sin 45^\circ = n \sin 61^\circ$$

$$n = 1.52 \times 0.707 / 0.875$$

$$\text{refractive index} = 1.23$$

This apparatus cannot be used to determine refractive indices smaller than a minimum value $n_{\min}$.

1 1 . 3

Determine, by considering the critical angle, the value of $n_{\min}$.

[1 mark]

TIR at the boundary when critical angle = 45° :

$$\sin 45^\circ = n_{\min} / 1.52, \quad n_{\min} = 1.52 \sin 45^\circ = 1.075$$

$$n_{\min} = \underline{1.1}$$

1 1 . 4

Explain why refractive indices smaller than $n_{\min}$ cannot be measured with this apparatus.

[3 marks]

The angle of incidence at the first glass to material boundary is always 45° .

If $n < n_{\min}$, the critical angle at this boundary would be less than 45° ($\sin C = n / 1.52$), so the angle of incidence is greater than the critical angle.

Total internal reflection would occur at the glass to material boundary, so no light passes into the material and the angle of deviation from the horizontal cannot be measured.

9

END OF SECTION B

Turn over ►

Section C

Each of the questions in this section is followed by four responses, **A**, **B**, **C** and **D**.

For each question select the best response.

Only **one** answer per question is allowed.

For each question, completely fill in the circle alongside the appropriate answer.

CORRECT METHOD

WRONG METHODS

If you want to change your answer you must cross out your original answer as shown. 

If you wish to return to an answer previously crossed out, ring the answer you now wish to select as shown. 

You may do your working in the blank space around each question but this will not be marked. Do **not** use additional pages for this working.

1 2

The diagram shows a progressive transverse wave at one instant.
The direction of energy transfer is to the right.

What are the directions of movement of **P** and **Q** at this instant?
